## The 30 Year Horizon

<i>Manuel Bronstein</i>	<i>William Burge</i>	<i>Timothy Daly</i>
<i>James Davenport</i>	<i>Michael Dewar</i>	<i>Martin Dunstan</i>
<i>Albrecht Fortenbacher</i>	<i>Patrizia Gianni</i>	<i>Johannes Grabmeier</i>
<i>Jocelyn Guidry</i>	<i>Richard Jenks</i>	<i>Larry Lambe</i>
<i>Michael Monagan</i>	<i>Scott Morrison</i>	<i>William Sit</i>
<i>Jonathan Steinbach</i>	<i>Robert Sutor</i>	<i>Barry Trager</i>
<i>Stephen Watt</i>	<i>Jim Wen</i>	<i>Clifton Williamson</i>

Volume 5: Axiom Interpreter

# Contents

<b>1</b>	<b>Credits</b>	<b>1</b>
<b>2</b>	<b>The Interpreter</b>	<b>5</b>
<b>3</b>	<b>The Fundamental Data Structures</b>	<b>7</b>
<b>4</b>	<b>Starting Axiom</b>	<b>9</b>
4.1	Variables Used . . . . .	9
4.2	Data Structures . . . . .	9
4.3	Functions . . . . .	9
4.3.1	Set the restart hook . . . . .	9
4.3.2	restart (restart) . . . . .	11
4.3.3	Starts the interpreter but do not read in profiles . . . . .	13
4.3.4	defvar \$quitTag . . . . .	13
4.3.5	defun runspad . . . . .	14
4.3.6	defun Reset the stack limits . . . . .	14
<b>5</b>	<b>Handling Input</b>	<b>15</b>
5.1	Streams . . . . .	15
5.1.1	defvar \$curinstream . . . . .	15
5.1.2	defvar \$curoutstream . . . . .	15
5.1.3	defvar \$errorinstream . . . . .	15
5.1.4	defvar \$erroroutstream . . . . .	16
5.1.5	defvar \$*eof* . . . . .	16
5.1.6	defvar \$InteractiveMode . . . . .	16
5.1.7	Top-level read-parse-eval-print loop . . . . .	16
5.1.8	defun ncIntLoop . . . . .	17
5.1.9	defun intloop . . . . .	17
5.1.10	defun SpadInterpretStream . . . . .	18
5.1.11	defvar \$promptMsg . . . . .	18
5.2	The Read-Eval-Print Loop . . . . .	20
5.2.1	defun intloopReadConsole . . . . .	20
5.3	Helper Functions . . . . .	21
5.3.1	Get the value of an environment variable . . . . .	21

5.3.2	defun init-memory-config . . . . .	22
5.3.3	Set spadroot to be the AXIOM shell variable . . . . .	23
5.3.4	Does the string start with this prefix? . . . . .	23
5.3.5	Get the current directory . . . . .	23
5.3.6	Prepend the absolute path to a filename . . . . .	24
5.3.7	Make the initial modemap frame . . . . .	24
5.3.8	defun nclloopEscaped . . . . .	24
5.3.9	Call the garbage collector . . . . .	25
5.3.10	defun reroot . . . . .	26
5.3.11	defun setCurrentLine . . . . .	27
5.3.12	Show the Axiom prompt . . . . .	27
5.3.13	defvar \$frameAlist . . . . .	28
5.3.14	defvar \$frameNumber . . . . .	28
5.3.15	defvar \$currentFrameNum . . . . .	28
5.3.16	defvar \$EndServerSession . . . . .	28
5.3.17	defvar \$NeedToSignalSessionManager . . . . .	28
5.3.18	defvar \$sockBufferLength . . . . .	28
5.3.19	READ-LINE in an Axiom server system . . . . .	29
5.3.20	Include a file into the stream . . . . .	30
5.3.21	defun intloopInclude0 . . . . .	31
5.3.22	defun nclloopInclude0 . . . . .	31
5.3.23	defun incStream . . . . .	31
5.3.24	defun incLude . . . . .	31
5.3.25	defmacro Rest . . . . .	32
5.3.26	defvar \$Top . . . . .	32
5.3.27	defvar \$IfSkipToEnd . . . . .	32
5.3.28	defvar \$IfKeepPart . . . . .	32
5.3.29	defvar \$IfSkipPart . . . . .	32
5.3.30	defvar \$ElseifSkipToEnd . . . . .	32
5.3.31	defvar \$ElseifKeepPart . . . . .	33
5.3.32	defvar \$ElseifSkipPart . . . . .	33
5.3.33	defvar \$ElseSkipToEnd . . . . .	33
5.3.34	defvar \$ElseKeepPart . . . . .	33
5.3.35	defvar \$Top? . . . . .	33
5.3.36	defvar \$If? . . . . .	33
5.3.37	defvar \$Elseif? . . . . .	34
5.3.38	defvar \$Else? . . . . .	34
5.3.39	defvar \$SkipEnd? . . . . .	34
5.3.40	defvar \$KeepPart? . . . . .	34
5.3.41	defvar \$SkipPart? . . . . .	34
5.3.42	defvar \$Skipping? . . . . .	35
5.3.43	defun incLude1 . . . . .	36
5.3.44	defun incRgen . . . . .	39
5.3.45	defun Delay . . . . .	40
5.3.46	defun incRgen1 . . . . .	40

<b>6</b>	<b>The Interpreter Syntax</b>	<b>41</b>
6.1	syntax assignment . . . . .	41
6.2	syntax blocks . . . . .	45
6.3	system clef . . . . .	47
6.4	syntax collection . . . . .	49
6.5	syntax for . . . . .	51
6.6	syntax if . . . . .	56
6.7	syntax iterate . . . . .	58
6.8	syntax leave . . . . .	59
6.9	syntax parallel . . . . .	61
6.10	syntax repeat . . . . .	64
6.11	syntax suchthat . . . . .	69
6.12	syntax syntax . . . . .	70
6.13	syntax while . . . . .	71
<b>7</b>	<b>System Command Handling</b>	<b>73</b>
7.0.1	defvar \$systemCommands . . . . .	73
7.1	Variables Used . . . . .	75
7.1.1	defvar \$systemCommands . . . . .	75
7.1.2	defvar \$syscommands . . . . .	77

7.2.6	defun ncloopPrefix? . . . . .	83
7.2.7	defun selectOptionLC . . . . .	83
7.2.8	defun selectOption . . . . .	83
<b>8</b>	<b>)abbreviations Command</b>	<b>85</b>
8.1	abbreviations man page . . . . .	85
8.2	Functions . . . . .	87
8.2.1	defun abbreviations . . . . .	87
8.2.2	defun abbreviationsSpad2Cmd . . . . .	88
8.2.3	defun listConstructorAbbreviations . . . . .	89
<b>9</b>	<b>)boot Command</b>	<b>91</b>
9.1	boot man page . . . . .	91
9.2	Functions . . . . .	92

<b>10 )browse Command</b>	<b>93</b>
10.1 browse man page . . . . .	93
10.2 Overview . . . . .	94
10.3 Browsers, MathML, and Fonts . . . . .	94
10.4 The axServer/multiServ loop . . . . .	96
10.5 The )browse command . . . . .	96
10.6 Variables Used . . . . .	97
10.7 Functions . . . . .	97
10.8 The server support code . . . . .	98
<b>11 )cd Command</b>	<b>99</b>
11.1 cd man page . . . . .	99
11.2 Variables Used . . . . .	100
11.3 Functions . . . . .	100
<b>12 )clear Command</b>	<b>101</b>
12.1 clear man page . . . . .	101
12.2 Variables Used . . . . .	103
12.2.1 defvar \$clearOptions . . . . .	103
12.3 Functions . . . . .	103
12.3.1 defun clear . . . . .	103
12.3.2 defun clearSpad2Cmd . . . . .	104
12.3.3 defun clearCmdSortedCaches . . . . .	105
12.3.4 defun clearCmdCompletely . . . . .	106
12.3.5 defun clearCmdAll . . . . .	107
12.3.6 defun clearCmdExcept . . . . .	107
12.3.7 defun clearCmdParts . . . . .	108
<b>13 )close Command</b>	<b>111</b>
13.1 close man page . . . . .	111
13.2 Functions . . . . .	112
13.2.1 defun queryClients . . . . .	112
13.2.2 defun close . . . . .	113
<b>14 )compiler Command</b>	<b>115</b>
14.1 compiler man page . . . . .	115
14.2 Functions . . . . .	121
14.2.1 defun compiler . . . . .	121
<b>15 )copyright Command</b>	<b>125</b>
15.1 copyright man page . . . . .	125
15.2 Functions . . . . .	131
15.2.1 defun copyright . . . . .	131

<b>16 )credits Command</b>	<b>133</b>
16.1 credits man page . . . . .	133
16.2 Variables Used . . . . .	133
16.3 Functions . . . . .	133
16.3.1 defun credits . . . . .	133
<b>17 )display Command</b>	<b>135</b>
17.1 display man page . . . . .	135
17.1.1 defvar \$displayOptions . . . . .	137
17.2 Functions . . . . .	137
17.2.1 defun display . . . . .	137

17.2.4 defun displayOperations . . . . .	139
17.2.5 defun yesanswer . . . . .	139
17.2.6 defun displayMacros . . . . .	140
17.2.7 defun sayExample . . . . .	142
17.2.8 defun cleanupLine . . . . .	143
<b>18 )edit Command</b>	<b>145</b>
18.1 edit man page . . . . .	145
18.2 Functions . . . . .	146
18.2.1 defun edit . . . . .	146
18.2.2 defun editSpad2Cmd . . . . .	147
<b>19 )fin Command</b>	<b>149</b>
19.1 fin man page . . . . .	149
19.2 Functions . . . . .	150
<b>20 )frame Command</b>	<b>151</b>
20.1 frame man page . . . . .	151
20.2 Variables Used . . . . .	154
20.2.1 Primary variables . . . . .	154
20.2.2 Used variables . . . . .	154
20.3 Data Structures . . . . .	155
20.3.1 Frames and the Interpreter Frame Ring . . . . .	155
20.4 Accessor Functions . . . . .	155
20.4.1 0th Frame Component – frameName . . . . .	155
20.4.2 defun frameName . . . . .	155
20.4.3 1st Frame Component – frameInteractive . . . . .	155
20.4.4 2nd Frame Component – frameIOIndex . . . . .	156
20.4.5 3rd Frame Component – frameHiFiAccess . . . . .	156
20.4.6 4th Frame Component – frameHistList . . . . .	156
20.4.7 5th Frame Component – frameHistListLen . . . . .	156
20.4.8 6th Frame Component – frameHistListAct . . . . .	156
20.4.9 7th Frame Component – frameHistRecord . . . . .	156

20.4.10	8th Frame Component – frameHistoryTable . . . . .	157
20.4.11	9th Frame Component – frameExposureData . . . . .	157
20.5	Functions . . . . .	157
20.5.1	Initializing the Interpreter Frame Ring . . . . .	157
20.5.2	Creating a List of all of the Frame Names . . . . .	158
20.5.3	Get Named Frame Environment (aka Interactive) . . . . .	158
20.5.4	Create a new, empty Interpreter Frame . . . . .	158
20.5.5	Collecting up the Environment into a Frame . . . . .	159
20.5.6	Update from the Current Frame . . . . .	160
20.5.7	Find a Frame in the Frame Ring by Name . . . . .	160
20.5.8	Update the Current Interpreter Frame . . . . .	161
20.5.9	Move to the next Interpreter Frame in Ring . . . . .	161
20.5.10	Change to the Named Interpreter Frame . . . . .	162
20.5.11	Move to the previous Interpreter Frame in Ring . . . . .	162
20.5.12	Add a New Interpreter Frame . . . . .	163
20.5.13	Close an Interpreter Frame . . . . .	164
20.5.14	Display the Frame Names . . . . .	164
20.5.15	Import items from another frame . . . . .	165
20.5.16	The top level frame command . . . . .	167
20.5.17	The top level frame command handler . . . . .	168
20.6	Frame File Messages . . . . .	169
<b>21</b>	<b>)help Command</b>	<b>171</b>
21.1	help man page . . . . .	171
21.2	Functions . . . . .	174
21.2.1	The top level help command . . . . .	174
21.2.2	The top level help command handler . . . . .	174
21.2.3	defun newHelpSpad2Cmd . . . . .	175
<b>22</b>	<b>)history Command</b>	<b>177</b>
22.1	history man page . . . . .	177

<b>23 )include Command</b>	<b>217</b>
23.1 include man page . . . . .	217
23.2 Functions . . . . .	217
23.2.1 defun ncloopInclude1 . . . . .	217
23.2.2 Returns the first non-blank substring of the given string .	218
23.2.3 Open the include file and read it in . . . . .	218
23.2.4 Return the include filename . . . . .	218
23.2.5 Return the next token . . . . .	219
<b>24 )library Command</b>	<b>221</b>
24.1 library man page . . . . .	221
<b>25 )lisp Command</b>	<b>223</b>
25.1 lisp man page . . . . .	223
25.2 Functions . . . . .	224
<b>26 )load Command</b>	<b>225</b>
26.1 load man page . . . . .	225
<b>27 )ltrace Command</b>	<b>227</b>
27.1 ltrace man page . . . . .	227
27.2 Variables Used . . . . .	228
27.3 Functions . . . . .	228
<b>28 )pquit Command</b>	<b>229</b>
28.1 pquit man page . . . . .	229
28.2 Functions . . . . .	230
28.2.1 The top level pquit command . . . . .	230
28.2.2 The top level pquit command handler . . . . .	230
<b>29 )quit Command</b>	<b>233</b>
29.1 quit man page . . . . .	233
29.2 Functions . . . . .	234
29.2.1 The top level quit command . . . . .	234
29.2.2 The top level quit command handler . . . . .	234
29.2.3 Leave the Axiom interpreter . . . . .	235
<b>30 )read Command</b>	<b>237</b>
30.1 read man page . . . . .	237
<b>31 )savesystem Command</b>	<b>239</b>
31.1 savesystem man page . . . . .	239

<b>32 )set Command</b>	<b>241</b>
32.1 set man page . . . . .	241
32.2 Overview . . . . .	243
32.3 Variables Used . . . . .	243
32.4 Functions . . . . .	243
32.4.1 Initialize the set variables . . . . .	243
32.4.2 Reset the workspace variables . . . . .	245
32.4.3 Display the set option information . . . . .	246
32.4.4 Display the set variable settings . . . . .	248
32.4.5 Translate options values to t or nil . . . . .	249
32.4.6 Translate t or nil to option values . . . . .	249
32.5 The list structure . . . . .	250
32.6 breakmode . . . . .	251
32.6.1 defvar \$BreakMode . . . . .	251
32.7 debug . . . . .	252
32.8 debug lambda type . . . . .	252
32.8.1 defvar \$lambdatype . . . . .	252
32.9 debug dalymode . . . . .	253

## New Foreword

On October 1, 2001 Axiom was withdrawn from the market and ended life as a commercial product. On September 3, 2002 Axiom was released under the Modified BSD license, including this document. On August 27, 2003 Axiom was released as free and open source software available for download from the Free Software Foundation's website, Savannah.

Work on Axiom has had the generous support of the Center for Algorithms and Interactive Scientific Computation (CAISS) at City College of New York. Special thanks go to Dr. Gilbert Baumslag for his support of the long term goal.

The online version of this documentation is roughly 1000 pages. In order to make printed versions we've broken it up into three volumes. The first volume is tutorial in nature. The second volume is for programmers. The third volume is reference material. We've also added a fourth volume for developers. All of these changes represent an experiment in print-on-demand delivery of documentation. Time will tell whether the experiment succeeded.

Axiom has been in existence for over thirty years. It is estimated to contain about three hundred man-years of research and has, as of September 3, 2003, 143 people listed in the credits. All of these people have contributed directly or indirectly to making Axiom available. Axiom is being passed to the next generation. I'm looking forward to future milestones.

With that in mind I've introduced the theme of the "30 year horizon". We must invent the tools that support the Computational Mathematician working 30 years from now. How will research be done when every bit of mathematical knowledge is online and instantly available? What happens when we scale Axiom by a factor of 100, giving us 1.1 million domains? How can we integrate theory with code? How will we integrate theorems and proofs of the mathematics with space-time complexity proofs and running code? What visualization tools are needed? How do we support the conceptual structures and semantics of mathematics in effective ways? How do we support results from the sciences? How do we teach the next generation to be effective Computational Mathematicians?

The "30 year horizon" is much nearer than it appears.

Tim Daly

# Chapter 1

## Credits

Axiom has a very long history and many people have contributed to the effort, some in large ways and some in small ways. Any and all effort deserves recognition. There is no other criteria than contribution of effort. We would like to acknowledge and thank the following people:

## Chapter 2

# The Interpreter

The Axiom interpreter is a large common lisp program. It has several forms of interaction and run from terminal in a standalone fashion, run under the control of a session handler program, run as a web server, or run in a unix pipe.

## Chapter 3

# The Fundamental Data Structures

## Chapter 4

# Starting Axiom

Axiom starts by invoking a function value of the lisp symbol `*top-level-hook*`. The function invocation path to from this point until the prompt is approximates (skipping initializations):

```
lisp -> restart
      -> |spad|
      -> |runspad|
      -> |ncTopLevel|
      -> |ncIntLoop|
      -> |intloop|
      -> |SpadInterpretStream|
      -> |intloopReadConsole|
```

The `—intloopReadConsole—` function does tail-recursive calls to itself (don't break this) and never exits.

### 4.1 Variables Used

### 4.2 Data Structures

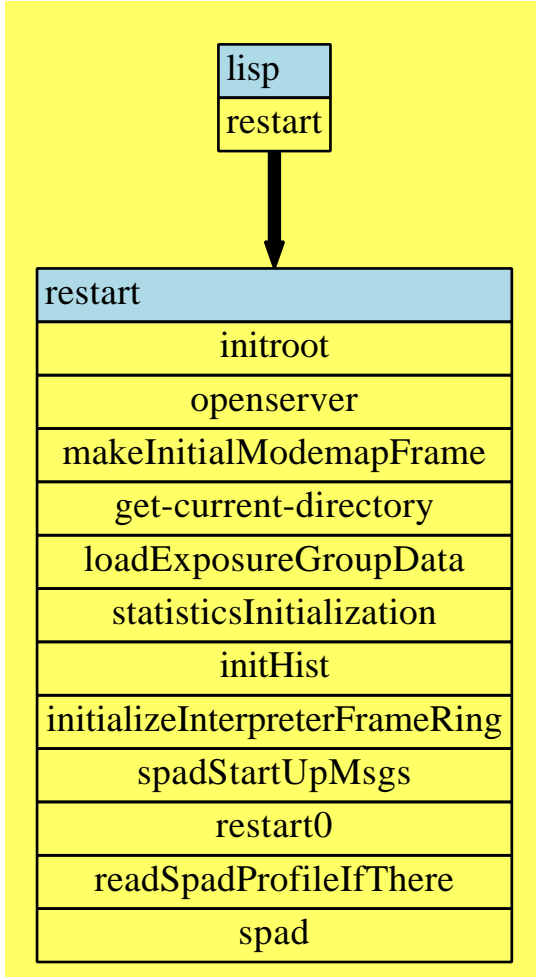

### 4.3 Functions

#### 4.3.1 Set the restart hook

When a lisp image containing code is reloaded there is a hook to allow a function to be called. In our case it is the restart function which is the entry to the Axiom interpreter.

*(defun set-restart-hook)≡*

```
(defun set-restart-hook ()  
  "Set the restart hook"  
  #+KCL (setq system::*top-level-hook* 'restart)  
  #+Lucid (setq boot::restart-hook 'restart)  
  'restart  
)
```

4.3.2 `restart (restart)`

The `restart` function is the real root of the world. It sets up memory if we are working in a GCL/akcl version of the system.

The `compiler::*compile-verbose*` flag has been set to `nil` globally. We do not want to know about the microsteps of GCL's compile facility.

The `compiler::*suppress-compiler-warnings*` flag has been set to `t`. We do not care that certain generated variables are not used.

The `compiler::*suppress-compiler-notes*` flag has been set to `t`. We do not care that tail recursion occurs.

It sets the current package to be the "BOOT" package which is the standard package in which the interpreter runs.

The "initroot" (5.3.3 p 23) function sets global variables that depend on the

AXIOM shell variable. These are needed to find basic files like `s2-us.msgs`, which contains the error message text.

The “`openserver`” (46.0.17 p 493) function tried to set up the socket connection used for things like `hyperdoc`. The `$openServerIfTrue` variable starts true, which implies trying to start a server.

The `$IOindex` variable is the number associated with the input prompt. Every successful expression evaluated increments this number until a `)clear all` resets it. Here we set it to the initial value.

Axiom has multiple frames that contain independent information about a computation. There can be several frames at any one time and you can shift back and forth between the frames. By default, the system starts in “`frame0`” (try the `)frame names` command). See the Frame Mechanism chapter (?? page ??).

The `$InteractiveFrame` variable contains the state information related to the current frame, which includes things like the last value, the value of all of the variables, etc.

The “`printLoadMsgs`” (53.2.42 p 533) variable controls whether load messages will be output as library routines are loaded. We enable this by default. It can be changed by using `)set message autoload`.

The “`current-directory`” (?? p ??) variable is set to the current directory. This is used by the `)cd` function and some of the compile routines.

The “`loadExposureGroupData`” (48.0.19 p 497) function initializes several variables with the exposure groups. These lists limit the user visible names in order to keep the user and interpreter from being confused by names which are common but whose signatures are for internal algebra uses.

The “`statisticsInitialization`” (49.0.20 p 499) function initializes variables used to collect statistics. Currently, only the garbage collector information is initialized.

```
(defun restart)≡
  (defun restart ()
    (declare (special $openServerIfTrue $SpadServerName |$SpadServer|
                     |$IOindex| |$InteractiveFrame| |$printLoadMsgs| $current-directory
                     |$displayStartMsgs| |$currentLine|))

```

### 4.3.3 Starts the interpreter but do not read in profiles

```

⟨defun spad⟩≡
  (defun |spad| ()
    "Starts the interpreter but do not read in profiles"
    (let (|$PrintCompilerMessageIfTrue| |$inLispVM|)
      (declare (special |$PrintCompilerMessageIfTrue| |$inLispVM|))
      (setq |$PrintCompilerMessageIfTrue| nil)
      (setq |$inLispVM| nil)
      (|setOutputAlgebra| '|%initialize%|)
      (|runspad|)
      '|EndOfSpad|))

```

### 4.3.4 defvar \$quitTag

```

⟨initvars⟩+≡
  (defvar |$quitTag| system::*quit-tag*)

```

### 4.3.5 defun runspad

```

<defun runspad>≡
  (defun |runspad| ()
    (prog (mode)
      (declare (special |$quitTag|))
      (return
        (seq
          (progn
            (setq mode '|restart|)
            (do ()
              ((null (eq mode '|restart|)) nil)
              (seq
                (exit
                  (progn
                    (|resetStackLimits|)
                    (catch |$quitTag|
                      (catch '|coerceFailure|
                        (setq mode (catch '|top_level| (|ncTopLevel|))))))))))))))

```

### 4.3.6 defun Reset the stack limits

```

<defun resetStackLimits>≡
  (defun |resetStackLimits| ()
    "Reset the stack limits"
    (system:reset-stack-limits))

```

## Chapter 5

# Handling Input

### 5.1 Streams

#### 5.1.1 defvar \$curinstream

The curinstream variable is set to the value of the **\*standard-input\*** common lisp variable in ncIntLoop. While not using the “dollar” convention this variable is still “global”.

```
<initvars>+≡  
  (defvar curinstream (make-synonym-stream '*standard-input*))
```

#### 5.1.2 defvar \$curoutstream

The curoutstream variable is set to the value of the **\*standard-output\*** common lisp variable in ncIntLoop. While not using the “dollar” convention this variable is still “global”.

```
<initvars>+≡  
  (defvar curoutstream (make-synonym-stream '*standard-output*))
```

#### 5.1.3 defvar \$errorinstream

```
<initvars>+≡  
  (defvar errorinstream (make-synonym-stream '*terminal-io*))
```

### 5.1.4 defvar \$erroroutstream

```

<initvars>+≡
  (defvar erroroutstream (make-synonym-stream '*terminal-io*))

```

### 5.1.5 defvar \$\*eof\*

```

<initvars>+≡
  (defvar *eof* nil)

```

### 5.1.6 defvar \$InteractiveMode

```

<initvars>+≡
  (defvar |$InteractiveMode| t)

```

### 5.1.7 Top-level read-parse-eval-print loop

Top-level read-parse-eval-print loop for the interpreter. Uses the Bill Burge's parser.

```

<defun ncTopLevel>≡
  (defun |ncTopLevel| ()
    "Top-level read-parse-eval-print loop"
    (let (|$e| $spad $newspad $boot |$InteractiveMode| *eof* in-stream)
      (declare (special |$e| $spad $newspad $boot |$InteractiveMode| *eof*
        in-stream |$InteractiveFrame|))
      (setq in-stream curinstream)
      (setq *eof* nil)
      (setq |$InteractiveMode| t)
      (setq $boot nil)
      (setq $newspad t)
      (setq $spad t)
      (setq |$e| |$InteractiveFrame|)
      (|ncIntLoop|)))

```

### 5.1.10 defun SpadInterpretStream

The SpadInterpretStream function takes three arguments

`str` This is passed as an argument to `intloopReadConsole`

`source` This is the name of a source file but appears not to be used. It is set to the list `(tim daly ?)`.

`interactive?` If this is false then various messages are suppressed and input does not use piles. If this is true then the library loading routines might output messages and piles are expected on input (as from a file).

The system commands are handled by the function kept in the “hook” variable `$systemCommandFunction` which has the default function `InterpExecuteSpadSystemCommand`. Thus, when a system command is entered this function is called.

The `$promptMsg` variable is set to the constant `S2CTP023`. This constant points to a message in `src/doc/messages/s2-us.messages`. This message does nothing but print the argument value.

### 5.1.11 defvar \$promptMsg

```
<initvars>+≡
  (defvar |$promptMsg| 'S2CTP023)
```

```

⟨defun SpadInterpretStream⟩≡
  (defun |SpadInterpretStream| (str source interactive?)
    (let (|$promptMsg| |$systemCommandFunction|
          |$ncMsgList| |$erMsgToss| |$lastPos| |$inclAssertions|
          |$okToExecuteMachineCode| |$newcompErrorCount| |$newcompMode|
          |$libQuiet| |$fn|)
      (declare (special |$promptMsg|
                        |$systemCommandFunction| |$ncMsgList| |$erMsgToss| |$lastPos|
                        |$inclAssertions| |$okToExecuteMachineCode| |$newcompErrorCount|
                        |$newcompMode| |$libQuiet| |$fn| |$npos|))
        (setq |$fn| source)
        (setq |$libQuiet| (null interactive?))
        (setq |$newcompMode| nil)
        (setq |$newcompErrorCount| 0)
        (setq |$okToExecuteMachineCode| t)
        (setq |$inclAssertions| (list 'aix '|CommonLisp|))
        (setq |$lastPos| |$npos|)
        (setq |$erMsgToss| nil)
        (setq |$ncMsgList| nil)
        (setq |$systemCommandFunction| #'|InterpExecuteSpadSystemCommand|)
        (setq |$promptMsg| 's2ctp023)
        (if interactive?
            (progn
              (princ (mkprompt))
              (|intloopReadConsole| "" str))
            (|intloopInclude| source 0))))

```

## 5.2 The Read-Eval-Print Loop

### 5.2.1 `defun intloopReadConsole`

Note that this function relies on the fact that lisp can do tail-recursion. The function recursively invokes itself.

The `serverReadLine` function is a special readline function that handles communication with the session manager code, which is a separate process running in parallel.

We read a line from standard input.

- If it is a null line then we exit Axiom.
- If it is a zero length line we prompt and recurse
- If `$dalymode` and open-paren we execute lisp code, prompt and recurse  
The `$dalymode` will interpret any input that begins with an open-paren as a lisp expression rather than Axiom input. This is useful for debugging purposes when most of the input lines will be lisp. Setting `$dalymode` non-nil will certainly break user expectations and is to be used with caution.
- If it is “)fi” or “)fin” we drop into lisp. Use the `(restart)` function to return to the interpreter loop.
- If it starts with “)” we process the command, prompt, and recurse
- If it is a command then we remember the current line, process the command, prompt, and recurse.
- If the input has a trailing underscore (Axiom line-continuation) then we cut off the continuation character and pass the truncated string to ourselves, prompt, and recurse
- otherwise we process the input, prompt, and recurse.

Notice that all but two paths (a null input or a “)fi” or a “)fin”) will end up as a recursive call to ourselves.

```
(defun intloopReadConsole)≡
  (defun |intloopReadConsole| (b n)
    (declare (special $dalymode))
    (let (c d pfx input)
      (setq input (|serverReadLine| *standard-input*))
      (when (null (stringp input)) (|leaveScratchpad|))
      (when (eql (length input) 0)
        (princ (mkprompt))
        (|intloopReadConsole| "" n))
      (when (and $dalymode (|intloopPrefix?| "(" input))
```

```

(|intnplisp| input)
(princ (mkprompt))
(|intloopReadConsole| "" n))
(setq pfx (|intloopPrefix?| ")fi" input))
(when (and pfx (or (string= pfx ")fi") (string= pfx ")fin")))

## 5.3 Helper Functions

### 5.3.1 Get the value of an environment variable

```

⟨defun getenviron⟩≡
(defun getenviron (var)
  "Get the value of an environment variable"
  #+allegro (sys::getenv (string var))
  #+clisp (ext:getenv (string var))
  #+(or cmu scl)
  (cdr
   (assoc (string var) ext:*environment-list* :test #'equalp :key #'string))
  #+(or kcl akcl gcl) (si::getenv (string var))
  #+lispworks (lw:environment-variable (string var))
  #+lucid (lcl:environment-variable (string var))
  #+mcl (ccl::getenv var)
  #+sbcl (sb-ext:posix-getenv var)
  )

```

### 5.3.2 defun init-memory-config

Austin-Kyoto Common Lisp (AKCL), now known as Gnu Common Lisp (GCL) requires some changes to the default memory setup to run Axiom efficiently. This function performs those setup commands.

```

<defun init-memory-config>≡
  (defun init-memory-config (&key
                             (cons 500)
                             (fixnum 200)
                             (symbol 500)
                             (package 8)
                             (array 400)
                             (string 500)
                             (cfun 100)
                             (cpages 3000)
                             (rpages 1000)
                             (hole 2000) )
    ;; initialize AKCL memory allocation parameters
    #+:AKCL
    (progn
      (system:allocate 'cons cons)
      (system:allocate 'fixnum fixnum)
      (system:allocate 'symbol symbol)
      (system:allocate 'package package)
      (system:allocate 'array array)
      (system:allocate 'string string)
      (system:allocate 'cfun cfun)
      (system:allocate-contiguous-pages cpages)
      (system:allocate-relocatable-pages rpages)
      (system:set-hole-size hole))
    #-:AKCL
    nil)

```

### 5.3.3 Set spadroot to be the AXIOM shell variable

Sets up the system to use the **AXIOM** shell variable if we can and default to the **\$spadroot** variable (which was the value of the **AXIOM** shell variable at build time) if we can't.

Called from “restart” (4.3.2 p 11).

```
<defun initroot>≡
  (defun initroot (&optional (newroot (getenv "AXIOM"))))
    "Set spadroot to be the AXIOM shell variable"
    (declare (special $spadroot))
    (reroot (or newroot $spadroot (error "setenv AXIOM or (setq $spadroot)"))))
```

### 5.3.4 Does the string start with this prefix?

If the prefix string is the same as the whole string initial characters –R(ignore spaces in the whole string) then we return the whole string minus any leading spaces.

```
<defun intloopPrefix?>≡
  (defun |intloopPrefix?| (prefix whole)
    "Does the string start with this prefix?"
    (let ((newprefix (string-left-trim '(\space) prefix))
          (newwhole (string-left-trim '(\space) whole)))
      (when (<= (length newprefix) (length newwhole))
        (when (string= newprefix newwhole :end2 (length prefix))
          newwhole))))
```

### 5.3.5 Get the current directory

```
<defun get-current-directory>≡
  #+:cmu
  (defun get-current-directory ()
    "Get the current directory"
    (namestring (extensions::default-directory)))

  #+(or :akcl :gcl)
  (defun get-current-directory ()
    "Get the current directory"
    (namestring (truename "")))
```

### 5.3.6 Prepend the absolute path to a filename

Prefix a filename with the **AXIOM** shell variable.

```
<defun make-absolute-filename>≡
  (defun make-absolute-filename (name)
    "Prepend the absolute path to a filename"
    (declare (special $spadroot))
    (concatenate 'string $spadroot name))
```

### 5.3.7 Make the initial modemap frame

```
<defun makeInitialModemapFrame>≡
  (defun |makeInitialModemapFrame| ()
    "Make the initial modemap frame"
    (declare (special |$InitialModemapFrame|))
    (copy |$InitialModemapFrame|))
```

### 5.3.8 defun ncloopEscaped

The ncloopEscaped function will return true if the last non-blank character of a line is an underscore, the Axiom line-continuation character. Otherwise, it returns nil.

```
<defun ncloopEscaped>≡
  (defun |ncloopEscaped| (x)
    (let ((l (length x)))
      (dotimes (i l)
        (when (char= (char x (- l i 1)) #\_) (return t))
        (unless (char= (char x (- l i 1)) #\space) (return nil))))))
```

### 5.3.9 Call the garbage collector

Call the garbage collector on various platforms.

```
(defun reclaim)≡
  #+abcl
  (defun reclaim () "Call the garbage collector" (ext::gc))
  #+:allegro
  (defun reclaim () "Call the garbage collector" (excl::gc t))
  #+:CCL
  (defun reclaim () "Call the garbage collector" (gc))
  #+clisp
  (defun reclaim ()
    "Call the garbage collector"
    (#+lisp=cl ext::gc #-lisp=cl lisp::gc))
  #+(or :cmulisp :cmu)
  (defun reclaim () "Call the garbage collector" (ext:gc))
  #+cormanlisp
  (defun reclaim () "Call the garbage collector" (cl::gc))
  #+(OR IBCL KCL GCL)
  (defun reclaim () "Call the garbage collector" (si::gbc t))
  #+lispworks
  (defun reclaim () "Call the garbage collector" (hcl::normal-gc))
  #+Lucid
  (defun reclaim () "Call the garbage collector" (lcl::gc))
  #+sbcl
  (defun reclaim () "Call the garbage collector" (sb-ext::gc))
```

### 5.3.10 defun reroot

The reroot function is used to reset the important variables used by the system. In particular, these variables are sensitive to the **AXIOM** shell variable. That variable is renamed internally to be **\$spadroot**. The **reroot** function will change the system to use a new root directory and will have the same effect as changing the **AXIOM** shell variable and rerunning the system from scratch. Note that we have changed from the NAG distribution back to the original form. If you need the NAG version you can push **:tpd** on the **\*features\*** variable before compiling this file. A correct call looks like:

```
(in-package "BOOT")
(reroot "/spad/mnt/${SYS}")
```

where the **\${SYS}** variable is the same one set at build time.

```
<defun reroot>≡
(defun reroot (dir)
  (declare (special $spadroot $directory-list $relative-directory-list
    $library-directory-list $relative-library-directory-list
    |$defaultMsgDatabaseName| |$msgDatabaseName| $current-directory))
  (setq $spadroot dir)
  (setq $directory-list
    (mapcar #'make-absolute-filename $relative-directory-list))
  (setq $library-directory-list
    (mapcar #'make-absolute-filename $relative-library-directory-list))
  (setq |$defaultMsgDatabaseName|
    (pathname (make-absolute-filename "/doc/msgsgs/s2-us.msgsg")))
  (setq |$msgDatabaseName| ())
  (setq $current-directory $spadroot))
```

### 5.3.11 defun setCurrentLine

Remember the current line. The cases are:

- If there is no `$currentLine` set it to the input
- Is the current line a string and the input a string? Make them into a list
- Is `$currentLine` not a cons cell? Make it one.
- Is the input a string? Cons it on the end of the list.
- Otherwise stick it on the end of the list

Note I suspect the last two cases do not occur in practice since they result in a dotted pair if the input is not a cons. However, this is what the current code does so I won't change it.

```
(defun setCurrentLine)≡
  (defun |setCurrentLine| (s)
    (declare (special |$currentLine|))
    (cond
      ((null |$currentLine|) (setq |$currentLine| s))
      ((and (stringp |$currentLine|) (stringp s))
       (setq |$currentLine| (list |$currentLine| s)))
      ((not (consp |$currentLine|)) (setq |$currentLine| (cons |$currentLine| s)))
      ((stringp s) (rplacd (last |$currentLine|) (cons s nil)))
      (t (rplacd (last |$currentLine|) s)))
    |$currentLine|)
```

### 5.3.12 Show the Axiom prompt

```
(defun mkprompt)≡
  (defun mkprompt ()
    "Show the Axiom prompt"
    (declare (special |$inputPromptType| |$IOindex| |$interpreterFrameName|))
    (case |$inputPromptType|
      (|none| "")
      (|plain| "-> ")
      (|step| (strconc "(" (stringimage |$IOindex|) ") -> "))
      (|frame|
       (strconc (stringimage |$interpreterFrameName|) " ("
                 (stringimage |$IOindex|) ") -> "))
      (t (strconc (stringimage |$interpreterFrameName|) " ["
                   (substring (currenttime) 8 nil) "]" ["
                     (stringimage |$IOindex|) "]" -> "))))))
```

**5.3.13 defvar \$frameAlist**

```
<initvars>+≡  
(defvar |$frameAlist| nil)
```

**5.3.14 defvar \$frameNumber**

```
<initvars>+≡  
(defvar |$frameNumber| 0)
```

**5.3.15 defvar \$currentFrameNum**

```
<initvars>+≡  
(defvar |$currentFrameNum| 0)
```

**5.3.16 defvar \$EndServerSession**

```
<initvars>+≡  
(defvar |$EndServerSession| nil)
```

**5.3.17 defvar \$NeedToSignalSessionManager**

```

  (t (cons (|x1CmdBug| eb str lno ufos) |StreamNil|))))))

```

#### 5.3.44 defun incRgen

Note that incRgen1 recursively calls this function.

```

⟨defun incRgen⟩≡
  (defun |incRgen| (s)
    (|Delay| (function |incRgen1|) (list s)))

```

**5.3.45 defun Delay**

```

<defun Delay>≡
  (defun |Delay| (f x)
    (cons '|nonnullstream| (cons f x)))

<initvars>+≡
  (defvar |StreamNil| (list '|nullstream|))

<postvars>≡
  (eval-when (eval load)
    (setq |StreamNil| (list '|nullstream|)))

```

**5.3.46 defun incRgen1**

This function reads a line from the stream and then conses it up with a recursive call to incRgen. Note that incRgen recursively wraps this function in a delay list.

```

<defun incRgen1>≡
  (defun |incRgen1| (&rest z)
    (let (a s)
      (declare (special |StreamNil|))
      (setq s (car z))
      (setq a (|shoeread-line| s))
      (if (null a)
        (progn
          (close s)
          |StreamNil|)
        (cons a (|incRgen| s)))))

```

## Chapter 6

# The Interpreter Syntax

### 6.1 syntax assignment

*<assignment.help>*≡

Immediate, Delayed, and Multiple Assignment

=====  
Immediate Assignment  
=====

A variable in Axiom refers to a value. A variable has a name beginning with an uppercase or lowercase alphabetic character, "%", or "!". Successive characters (if any) can be any of the above, digits, or "?". Case is distinguished. The following are all examples of valid, distinct variable names:

a	tooBig?	a1B2c3%!?
A	%j	numberOfPoints
beta6	%J	numberofpoints

The "!=" operator is the immediate assignment operator. Use it to associate a value with a variable. The syntax for immediate assignment for a single variable is:

variable := expression

The value returned by an immediate assignment is the value of expression.

a := 1

```

1
Type: PositiveInteger

```

The right-hand side of the expression is evaluated, yielding 1. The value is then assigned to a.

```

b := a
1
Type: PositiveInteger

```

The right-hand side of the expression is evaluated, yielding 1. This value is then assigned to b. Thus a and b both have the value 1 after the sequence of assignments.

```

a := 2
2
Type: PositiveInteger

```

What is the value of b if a is assigned the value 2?

```

b
1
Type: PositiveInteger

```

The value of b is left unchanged.

This is what we mean when we say this kind of assignment is immediate. The variable b has no dependency on a after the initial assignment. This is the usual notion of assignment in programming languages such as C, Pascal, and Fortran.

```

=====
Delayed Assignment
=====

```

Axiom provides delayed assignment with "==". This implements a delayed evaluation of the right-hand side and dependency checking. The syntax for delayed assignment is

```
variable == expression
```

The value returned by a delayed assignment is the unique value of Void.

```

a == 1
Type: Void

```

```
b == a
      Type: Void
```

Using a and b as above, these are the corresponding delayed assignments.

```
a
  Compiling body of rule a to compute value of type PositiveInteger
  1
      Type: PositiveInteger
```

The right-hand side of each delayed assignment is left unevaluated until the variables on the left-hand sides are evaluated.

```
b
  Compiling body of rule b to compute value of type PositiveInteger
  1
      Type: PositiveInteger
```

This gives the same results as before. But if we change a to 2

```
a == 2
  Compiled code for a has been cleared.
  Compiled code for b has been cleared.
  1 old definition(s) deleted for function or rule a
      Type: Void
```

Then a evaluates to 2, as expected

```
a
  Compiling body of rule a to compute value of type PositiveInteger
  2
      Type: PositiveInteger
```

but the value of b reflects the change to a

```
b
  Compiling body of rule b to compute value of type PositiveInteger
  2
      Type: PositiveInteger
```

#### =====

#### Multiple Immediate Assignments

#### =====

It is possible to set several variables at the same time by using a tuple of variables and a tuple of expressions. A tuple is a collection

of things separated by commas, often surrounded by parentheses. The syntax for multiple immediate assignment is

```
( var1, var2, ..., varN ) := ( expr1, expr2, ..., exprN )
```

The value returned by an immediate assignment is the value of `exprN`.

```
( x, y ) := ( 1, 2 )
2
```

Type: PositiveInteger

This sets `x` to 1 and `y` to 2. Multiple immediate assignments are parallel in the sense that the expressions on the right are all evaluated before any assignments on the left are made. However, the order of evaluation of these expressions is undefined.

```
( x, y ) := ( y, x )
1
```

Type: PositiveInteger

```
x
2
```

Type: PositiveInteger

The variable `x` now has the previous value of `y`.

```
y
1
```

Type: PositiveInteger

The variable `y` now has the previous value of `x`.

There is no syntactic form for multiple delayed assignments.

## 6.2 syntax blocks

`<blocks.help>≡`

```
=====
Blocks
=====
```

A block is a sequence of expressions evaluated in the order that they appear, except as modified by control expressions such as `leave`, `return`, `iterate`, and `if-then-else` constructions. The value of a block is the value of the expression last evaluated in the block.

To leave a block early, use `"=>"`. For example,

```
i < 0 => x
```

The expression before the `"=>"` must evaluate to true or false. The expression following the `"=>"` is the return value of the block.

A block can be constructed in two ways:

1. the expressions can be separated by semicolons and the resulting expression surrounded by parentheses, and
  2. the expressions can be written on succeeding lines with each line indented the same number of spaces (which must be greater than zero).
- A block entered in this form is called a pile

Only the first form is available if you are entering expressions directly to Axiom. Both forms are available in `.input` files. The syntax for a simple block of expressions entered interactively is

```
( expression1 ; expression2 ; ... ; expressionN )
```

The value returned by a block is the value of an `"=>"` expression, or `expressionN` if no `"=>"` is encountered.

In `.input` files, blocks can also be written in piles. The examples given here are assumed to come from `.input` files.

```
a :=
  i := gcd(234,672)
  i := 2*i**5 - i + 1
  1 / i

  1
-----
```

```
23323
```

```
Type: Fraction Integer
```

In this example, we assign a rational number to `a` using a block consisting of three expressions. This block is written as a pile. Each expression in the pile has the same indentation, in this case two spaces to the right of the first line.

```
a := ( i := gcd(234,672); i := 2*i**5 - i + 1; 1 / i )
```

```
1
```

```
-----
```

```
23323
```

```
Type: Fraction Integer
```

Here is the same block written on one line. This is how you are required to enter it at the input prompt.

```
( a := 1; b := 2; c := 3; [a,b,c] )
[1,2,3]
```

```
Type: List PositiveInteger
```

AAxiom gives you two ways of writing a block and the preferred way in an .input file is to use a pile. Roughly speaking, a pile is a block whose constituent expressions are indented the same amount. You begin a pile by starting a new line for the first expression, indenting it to the right of the previous line. You then enter the second expression on a new line, vertically aligning it with the first line. And so on. If you need to enter an inner pile, further indent its lines to the right of the outer pile. Axiom knows where a pile ends. It ends when a subsequent line is indented to the left of the pile or the end of the file.

1

## 6.3 system clef

*<clef.help>*≡

Entering printable keys generally inserts new text into the buffer (unless in overwrite mode, see below). Other special keys can be used to modify the text in the buffer. In the description of the keys below, `^n` means Control-`n`, or holding the CONTROL key down while pressing "`n`". Errors will ring the terminal bell.

```

^A/^E : Move cursor to beginning/end of the line.
^F/^B : Move cursor forward/backward one character.
^D      : Delete the character under the cursor.
^H, DEL : Delete the character to the left of the cursor.
^K      : Kill from the cursor to the end of line.
^L      : Redraw current line.
^O      : Toggle overwrite/insert mode. Initially in insert mode. Text
          added in overwrite mode (including yanks) overwrite
          existing text, while insert mode does not overwrite.
^P/^N   : Move to previous/next item on history list.
^R/^S   : Perform incremental reverse/forward search for string on
          the history list. Typing normal characters adds to the current
          search string and searches for a match. Typing ^R/^S marks
          the start of a new search, and moves on to the next match.
          Typing ^H or DEL deletes the last character from the search
          string, and searches from the starting location of the last search.
          Therefore, repeated DEL's appear to unwind to the match nearest
          the point at which the last ^R or ^S was typed. If DEL is
          repeated until the search string is empty the search location
          begins from the start of the history list. Typing ESC or
          any other editing character accepts the current match and
          loads it into the buffer, terminating the search.
^T      : Toggle the characters under and to the left of the cursor.
^Y      : Yank previously killed text back at current location. Note that
          this will overwrite or insert, depending on the current mode.
^U      : Show help (this text).
TAB     : Perform command completion based on word to the left of the cursor.
          Words are deemed to contain only the alphanumeric and the % ! ? _
          characters.
NL, CR  : returns current buffer to the program.

```

---

<sup>1</sup> “if” (6.6 p 56) “repeat” (6.10 p 64) “while” (6.13 p 71) “for” (6.5 p 51) “suchthat” (6.11 p 69) “parallel” (6.9 p 61) “lists” (?? p ??)

DOS and ANSI terminal arrow key sequences are recognized, and act like:

```
up      : same as ^P
down    : same as ^N
left    : same as ^B
right   : same as ^F
```

## 6.4 syntax collection

`<collection.help>=`

```
=====
Collection -- Creating Lists and Streams with Iterators
=====
```

All of the loop expressions which do not use the `repeat` `leave` or `iterate` words can be used to create lists and streams. For example:

This creates a simple list of the integers from 1 to 10:

```
list := [i for i in 1..10]
[1,2,3,4,5,6,7,8,9,10]
Type: List PositiveInteger
```

Create a stream of the integers greater than or equal to 1:

```
stream := [i for i in 1..]
[1,2,3,4,5,6,7,...]
Type: Stream PositiveInteger
```

This is a list of the prime numbers between 1 and 10, inclusive:

```
[i for i in 1..10 | prime? i]
[2,3,5,7]
Type: List PositiveInteger
```

This is a stream of the prime integers greater than or equal to 1:

```
[i for i in 1.. | prime? i]
[2,3,5,7,11,13,17,...]
Type: Stream PositiveInteger
```

This is a list of the integers between 1 and 10, inclusive, whose squares are less than 700:

```
[i for i in 1..10 while i*i < 700]
[1,2,3,4,5,6,7,8,9,10]
Type: List PositiveInteger
```

This is a stream of the integers greater than or equal to 1 whose squares are less than 700:

```
[i for i in 1.. while i*i < 700]
[1,2,3,4,5,6,7,...]
```

Type: Stream PositiveInteger

The general syntax of a collection is

```
[ collectExpression iterator1 iterator2 ... iteratorN ]
```

where each iterator is either a for or a while clause. The loop terminates immediately when the end test of any iterator succeeds or when a return expression is evaluated in collectExpression. The value returned by the collection is either a list or a stream of elements, one for each iteration of the collectExpression.

Be careful when you use while to create a stream. By default Axiom tries to compute and display the first ten elements of a stream. If the while condition is not satisfied quickly, Axiom can spend a long (potentially infinite) time trying to compute the elements. Use

```
)set streams calculate
```

to change the defaults to something else. This also affects the number of terms computed and displayed for power series. For the purposes of these examples we have use this system command to display fewer than ten terms.

## 6.5 syntax for

`<for.help>≡`

```
=====
for loops
=====
```

Axiom provide the `for` and `in` keywords in repeat loops, allowing you to integrate across all elements of a list, or to have a variable take on integral values from a lower bound to an upper bound. We shall refer to these modifying clauses of repeat loops as `for` clauses. These clauses can be present in addition to `while` clauses (See `)help while`). As with all other types of repeat loops, `leave` (see `)help leave`) can be used to prematurely terminate evaluation of the loop.

The syntax for a simple loop using `for` is

```
for iterator repeat loopbody
```

The iterator has several forms. Each form has an end test which is evaluated before `loopbody` is evaluated. A `for` loop terminates immediately when the end test succeeds (evaluates to true) or when a `leave` or `return` expression is evaluated in `loopbody`. The value returned by the loop is the unique value of `Void`.

```
=====
for i in n..m repeat
=====
```

If `for` is followed by a variable name, the `in` keyword and then an integer segment of the form `n..m`, the end test for this loop is the predicate `i > m`. The body of the loop is evaluated `m-n+1` times if this number is greater than 0. If this number is less than or equal to 0, the loop body is not evaluated at all.

The variable `i` has the value `n`, `n+1`, ..., `m` for successive iterations of the loop body. The loop variable is a local variable within the loop body. Its value is not available outside the loop body and its value and type within the loop body completely mask any outer definition of a variable with the same name.

```
for i in 10..12 repeat output(i**3)
1000
1331
1728
```

Type: Void

The loop prints the values of  $10^3$ ,  $11^3$ , and  $12^3$ .

```
a := [1,2,3]
[1,2,3]
Type: List PositiveInteger

for i in 1..#a repeat output(a.i)
1
2
3
Type: Void
```

Iterate across this list using "." to access the elements of a list and the # operation to count its elements.

This type of iteration is applicable to anything that uses ".". You can also use it with functions that use indices to extract elements.

```
m := matrix [[1,2],[4,3],[9,0]]
+-      +-
| 1  2 |
| 4  3 |
| 9  0 |
+-      +-
Type: Matrix Integer
```

Define m to be a matrix.

```
for i in 1..nrows(m) repeat output row(m.i)
[1,2]
[4,3]
[9,0]
Type: Void
```

Display the rows of m.

You can iterate with for-loops.

```
for i in 1..5 repeat
  if odd?(i) then iterate
  output(i)
2
4
Type: Void
```

Display the even integers in a segment.

```
=====
for i in n..m by s repeat
=====
```

By default, the difference between values taken on by a variable in loops such as

```
for i in n..m repeat ...
```

is 1. It is possible to supply another, possibly negative, step value by using the `by` keyword along with `for` and `in`. Like the upper and lower bounds, the step value following the `by` keyword must be an integer. Note that the loop

```
for i in 1..2 by 0 repeat output(i)
```

will not terminate by itself, as the step value does not change the index from its initial value of 1.

```
for i in 1..5 by 2 repeat output(i)
1
3
5
```

Type: Void

This expression displays the odd integers between two bounds.

```
for i in 5..1 by -2 repeat output(i)
5
3
1
```

Type: Void

Use this to display the numbers in reverse order.

```
=====
for i in n.. repeat
=====
```

If the value after the `".."` is omitted, the loop has no end test. A potentially infinite loop is thus created. The variable is given the successive values `n`, `n+1`, `n+2`, ... and the loop is terminated only if a `leave` or `return` expression is evaluated in the loop body. However, you may also add some other modifying clause on the `repeat`, for example,

a while clause, to stop the loop.

```
for i in 15.. while not prime?(i) repeat output(i)
15
16
```

Type: Void

This loop displays the integers greater than or equal to 15 and less than the first prime number greater than 15.

```
=====
for x in 1 repeat
=====
```

Another variant of the for loop has the form:

```
for x in list repeat loopbody
```

This form is used when you want to iterate directly over the elements of a list. In this form of the for loop, the variable *x* takes on the value of each successive element in *l*. The end test is most simply stated in English: "are there no more *x* in *l*?"

```
l := [0, -5, 3]
[0, -5, 3]
```

Type: List Integer

```
for x in l repeat output(x)
0
-5
3
```

Type: Void

This displays all of the elements of the list *l*, one per line.

Since the list constructing expression

```
expand [n..m]
```

creates the list

```
[n, n+1, ..., m]
```

you might be tempted to think that the loops

```
for i in n..m repeat output(i)
```

and

```
for x in expand [n..m] repeat output(x)
```

are equivalent. The second form first creates the expanded list (no matter how large it might be) and then does the iteration. The first form potentially runs in much less space, as the index variable `i` is simply incremented once per loop and the list is not actually created. Using the first form is much more efficient.

Of course, sometimes you really want to iterate across a specific list. This displays each of the factors of 2400000:

```
for f in factors(factor(2400000)) repeat output(f)
[factor= 2, exponent= 8]
[factor= 3, exponent= 1]
[factor= 5, exponent= 5]
Type: Void
```

## 6.6 syntax if

$\langle if.help \rangle \equiv$

```
=====
If-then-else
=====
```

Like many other programming languages, Axiom uses the three keywords `if`, `then`, and `else` to form conditional expressions. The `else` part of the conditional is optional. The expression between the `if` and `then` keywords is a predicate: an expression that evaluates to or is convertible to either `true` or `false`, that is, a `Boolean`.

The syntax for conditional expressions is

```
if predicate then expression1 else expression2
```

where the "`else expression2`" part is optional. The value returned from a conditional expression is `expression1` if the predicate evaluates to `true` and `expression2` otherwise. If no `else` clause is given, the value is always the unique value of `Void`.

An `if-then-else` expression always returns a value. If the `else` clause is missing then the entire expression returns the unique value of `Void`. If both clauses are present, the type of the value returned by `if` is obtained by resolving the types of the values of the two clauses.

The predicate must evaluate to, or be convertible to, an object of type `Boolean`: `true` or `false`. By default, the equal sign `"=`" creates an equation.

```
x + 1 = y
x + 1 = y
Type: Equation Polynomial Integer
```

This is an equation, not a boolean condition. In particular, it is an object of type `Equation Polynomial Integer`.

However, for predicates in `if` expressions, Axiom places a default target type of `Boolean` on the predicate and equality testing is performed. Thus you need not qualify the `"=`" in any way. In other contexts you may need to tell Axiom that you want to test for equality rather than create an equation. In these cases, use `"@"` and a target type of `Boolean`.

The compound symbol meaning "not equal" in Axiom is `"~="`. This can be used directly without a package call or a target specification. The expression `"a ~= b"` is directly translated to `"not(a = b)"`.

Many other functions have return values of type Boolean. These include `<`, `<=`, `>`, `>=`, `~=`, and `member?`. By convention, operations with names ending in `?` return Boolean values.

The usual rules for piles are suspended for conditional expressions. In .input files, the `then` and `else` keywords can begin in the same column as the corresponding `if` by may also appear to the right. Each of the following styles of writing if-then-else expressions is acceptable:

```
if i>0 then output("positive") else output("nonpositive")
```

```
if i>0 then output("positive")
    else output("nonpositive")
```

```
if i>0 then output("positive")
else output("nonpositive")
```

```
if i>0
then output("positive")
else output("nonpositive")
```

```
if i>0
    then output("positive")
    else output("nonpositive")
```

A block can follow the `then` or `else` keywords. In the following two assignments to `a`, the `then` and `else` clauses each are followed by two line piles. The value returned in each is the value of the second line.

```
a :=
  if i > 0 then
    j := sin(i * pi())
    exp(j + 1/j)
  else
    j := cos(i * 0.5 * pi())
    log(abs(j)**5 + i)
```

```
a :=
  if i > 0
    then
      j := sin(i * pi())
      exp(j + 1/j)
    else
      j := cos(i * 0.5 * pi())
```

```
log(abs(j)**5 + i)
```

These are both equivalent to the following:

```
a :=
  if i > 0 then (j := sin(i * pi()); exp(j + 1/j))
  else (j := cos(i * 0.5 * pi()); log(abs(j)**5 + i))
```

## 6.7 syntax iterate

*<iterate.help>*≡

```
=====
iterate in loops
=====
```

Axiom provides an iterate expression that skips over the remainder of a loop body and starts the next loop execution. We first initialize a counter.

```
i := 0
0
```

Type: NonNegativeInteger

Display the even integers from 2 to 5:

```
repeat
  i := i + 1
  if i > 5 then leave
  if odd?(i) then iterate
  output(i)
```

```
2
```

```
4
```

Type: Void

## 6.8 syntax leave

*<leave.help>*≡

```
=====
leave in loops
=====
```

The leave keyword is often more useful in terminating a loop. A leave causes control to transfer to the expression immediately following the loop. As loops always return the unique value of Void, you cannot return a value with leave. That is, leave takes no argument.

```
f() ==
  i := 1
  repeat
    if factorial(i) > 1000 then leave
    i := i + 1
  i
                                     Type: Void
```

This example is a modification of the last example in the previous section. Instead of using return we'll use leave.

```
f()
7
                                     Type: PositiveInteger
```

The loop terminates when factorial(i) gets big enough. The last line of the function evaluates to the corresponding "good" value of i and the function terminates, returning that value.

You can only use leave to terminate the evaluation of one loop. Lets consider a loop within a loop, that is, a loop with a nested loop. First, we initialize two counter variables.

```
(i,j) := (1,1)
1
                                     Type: PositiveInteger

repeat
  repeat
    if (i + j) > 10 then leave
    j := j + 1
  if (i + j) > 10 then leave
  i := i + 1
                                     Type: Void
```

Nested loops must have multiple leave expressions at the appropriate nesting level. How would you rewrite this so  $(i + j) > 10$  is only evaluated once?

```
=====
leave vs => in loop bodies
=====
```

Compare the following two loops:

<code>i := 1</code>	<code>i := 1</code>
<code>repeat</code>	<code>repeat</code>
<code>i := i + 1</code>	<code>i := i + 1</code>
<code>i &gt; 3 =&gt; i</code>	<code>if i &gt; 3 then leave</code>
<code>output(i)</code>	<code>output(i)</code>

In the example on the left, the values 2 and 3 for `i` are displayed but then the `"=>"` does not allow control to reach the call to `output` again. The loop will not terminate until you run out of space or interrupt the execution. The variable `i` will continue to be incremented because the `"=>"` only means to leave the block, not the loop.

In the example on the right, upon reaching 4, the `leave` will be executed, and both the block and the loop will terminate. This is one of the reasons why both `"=>"` and `leave` are provided. Using a `while` clause with the `"=>"` lets you simulate the action of `leave`.

## 6.9 syntax parallel

`<parallel.help>`≡

```
=====
parallel iteration
=====
```

Sometimes you want to iterate across two lists in parallel, or perhaps you want to traverse a list while incrementing a variable.

The general syntax of a repeat loop is

```
iterator1, iterator2, ..., iteratorN repeat loopbody
```

where each iterator is either a for or a while clause. The loop terminates immediately when the end test of any iterator succeeds or when a leave or return expression is evaluated in loopbody. The value returned by the loop is the unique value of Void.

```
l := [1,3,5,7]
   [1,3,5,7]
                                     Type: List PositiveInteger

m := [100,200]
   [100,200]
                                     Type: List PositiveInteger

sum := 0
     0
                                     Type: NonNegativeInteger
```

Here we write a loop to iterate across two lists, computing the sum of the pairwise product of the elements:

```
for x in l for y in m repeat
  sum := sum + x*y
                                     Type: Void
```

The last two elements of `l` are not used in the calculation because `m` has two fewer elements than `l`.

```
sum
700
                                     Type: NonNegativeInteger
```

This is the "dot product".

Next we write a loop to compute the sum of the products of the loop elements with their positions in the loop.

```

l := [2,3,5,7,11,13,17,19,23,29,31,37]
    [2,3,5,7,11,13,17,19,23,29,31,37]
                                Type: List PositiveInteger

sum := 0
    0
                                Type: NonNegativeInteger

for i in 0.. for x in l repeat sum := i * x
                                Type: Void

```

Here looping stops when the list `l` is exhausted, even though the `for i in 0..` specifies no terminating condition.

```

sum
407
                                Type: NonNegativeInteger

```

When `"|"` is used to qualify any of the `for` clauses in a parallel iteration, the variables in the predicates can be from an outer scope or from a `for` clause in or to the left of the modified clause.

This is correct:

```

for i in 1..10 repeat
  for j in 200..300 | odd? (i+j) repeat
    output [i,j]

```

But this is not correct. The variable `j` has not been defined outside the inner loop:

```

for i in 1..01 | odd? (i+j) repeat -- wrong, j not defined
  for j in 200..300 repeat
    output [i,j]

```

It is possible to mix several of repeat modifying clauses on a loop:

```

for i in 1..10
  for j in 151..160 | odd? j
    while i + j < 160 repeat
      output [i,j]
[1,151]

```

[3,153]

Type: Void

Here are useful rules for composing loop expressions:

1. while predicates can only refer to variables that are global (or in an outer scope) or that are defined in for clauses to the left of the predicate.
2. A "such that" predicate (something following "|") must directly follow a for clause and can only refer to variables that are global (or in an outer scope) or defined in the modified for clause or any for clause to the left.

## 6.10 syntax repeat

`<repeat.help>≡`

```
=====
Repeat Loops
=====
```

A loop is an expression that contains another expression, called the loop body, which is to be evaluated zero or more times. All loops contain the repeat keyword and return the unique value of Void. Loops can contain inner loops to any depth.

The most basic loop is of the form

```
repeat loopbody
```

Unless loopbody contains a leave or return expression, the loop repeats forever. The value returned by the loop is the unique value of Void.

Axiom tries to determine completely the type of every object in a loop and then to translate the loop body to Lisp or even to machine code. This translation is called compilation.

If Axiom decides that it cannot compile the loop, it issues a message stating the problem and then the following message:

```
We will attempt to step through and interpret the code
```

It is still possible that Axiom can evaluate the loop but in interpret-code mode.

```
=====
Return in Loops
=====
```

A return expression is used to exit a function with a particular value. In particular, if a return is in a loop within the function, the loop is terminated whenever the return is evaluated.

```
f() ==
i := 1
repeat
  if factorial(i) > 1000 then return i
  i := i + 1
```

Type: Void

```
f()
                                Type: Void
```

When factorial(i) is big enough, control passes from inside the loop all the way outside the function, returning the value of i (so we think). What went wrong? Isn't it obvious that this function should return an integer? Well, Axiom makes no attempt to analyze the structure of a loop to determine if it always returns a value because, in general, this is impossible. So Axiom has this simple rule: the type of the function is determined by the type of its body, in this case a block. The normal value of a block is the value of its last expression, in this case, a loop. And the value of every loop is the unique value of Void. So the return type of f is Void.

There are two ways to fix this. The best way is for you to tell Axiom what the return type of f is. You do this by giving f a declaration

```
f:() -> Integer
```

prior to calling for its value. This tells Axiom "trust me -- an integer is returned". Another way is to add a dummy expression as follows.

```
f() ==
  i := 1
  repeat
    if factorial(i) > 1000 then return i
    i := i + 1
  0
                                Type: Void
```

Note that the dummy expression will never be evaluated but it is the last expression in the function and will determine the return type.

```
f()
7
                                Type: PositiveInteger
```

```
=====
leave in loops
=====
```

The leave keyword is often more useful in terminating a loop. A leave causes control to transfer to the expression immediately following the loop. As loops always return the unique value of Void, you cannot return a value with leave. That is, leave takes no argument.

```

f() ==
  i := 1
  repeat
    if factorial(i) > 1000 then leave
    i := i + 1
  i

```

Type: Void

This example is a modification of the last example in the previous section. Instead of using return we'll use leave.

```

f()
7

```

Type: PositiveInteger

The loop terminates when factorial(i) gets big enough. The last line of the function evaluates to the corresponding "good" value of i and the function terminates, returning that value.

You can only use leave to terminate the evaluation of one loop. Lets consider a loop within a loop, that is, a loop with a nested loop. First, we initialize two counter variables.

```

(i,j) := (1,1)
1

```

Type: PositiveInteger

```

repeat
  repeat
    if (i + j) > 10 then leave
    j := j + 1
  if (i + j) > 10 then leave
  i := i + 1

```

Type: Void

Nested loops must have multiple leave expressions at the appropriate nesting level. How would you rewrite this so (i + j) > 10 is only evaluated once?

```

=====
leave vs => in loop bodies
=====

```

Compare the following two loops:

```

i := 1                                i := 1

```

<pre>repeat   i := i + 1   i &gt; 3 =&gt; i   output(i)</pre>	<pre>repeat   i := i + 1   if i &gt; 3 then leave   output(i)</pre>
---	---

In the example on the left, the values 2 and 3 for *i* are displayed but then the " $\Rightarrow$ " does not allow control to reach the call to output again. The loop will not terminate until you run out of space or interrupt the execution. The variable *i* will continue to be incremented because the " $\Rightarrow$ " only means to leave the block, not the loop.

In the example on the right, upon reaching 4, the leave will be executed, and both the block and the loop will terminate. This is one of the reasons why both " $\Rightarrow$ " and leave are provided. Using a while clause with the " $\Rightarrow$ " lets you simulate the action of leave.

```
=====
iterate in loops
=====
```

Axiom provides an iterate expression that skips over the remainder of a loop body and starts the next loop execution. We first initialize a counter.

```
i := 0
0
Type: NonNegativeInteger
```

Display the even integers from 2 to 5:

```
repeat
  i := i + 1
  if i > 5 then leave
  if odd?(i) then iterate
  output(i)
2
4
Type: Void
```

Also See:

- o )help blocks
- o )help if
- o )help while
- o )help for
- o )help suchthat
- o )help parallel

- o `)help lists`

2

## 6.11 syntax suchthat

*<suchthat.help>*≡

```
=====
Such that predicates
=====
```

A for loop can be followed by a "|" and then a predicate. The predicate qualifies the use of the values from the iterator that follows the for. Think of the vertical bar "|" as the phrase "such that".

```
for n in 0..4 | odd? n repeat output n
1
3
```

Type: Void

This loop expression prints out the integers n in the given segment such that n is odd.

A for loop can also be written

```
for iterator | predicate repeat loopbody
```

which is equivalent to:

```
for iterator repeat if predicate then loopbody else iterate
```

The predicate need not refer only to the variable in the for clause. Any variable in an outer scope can be part of the predicate.

```
for i in 1..50 repeat
  for j in 1..50 | factorial(i+j) < 25 repeat
    output [i,j]
[1,1]
[1,2]
[1,3]
[2,1]
[2,2]
[3,1]
```

Type: Void

---

<sup>2</sup> "blocks" (6.2 p 45) "if" (6.6 p 56) "while" (6.13 p 71) "for" (6.5 p 51) "suchthat" (6.11 p 69) "parallel" (6.9 p 61) "lists" (?? p ??)

## 6.12 syntax syntax

$\langle syntax.help \rangle \equiv$

The Axiom Interactive Language has the following features documented here.

More information is available by typing

```
)help feature
```

where feature is one of:

```
assignment -- Immediate and delayed assignments
blocks      -- Blocks of expressions
collection  -- creating lists with iterators
for         -- for loops
if          -- If-then-else statements
iterate     -- using iterate in loops
leave       -- using leave in loops
parallel    -- parallel iterations
repeat      -- repeat loops
suchthat    -- suchthat predicates
while       -- while loops
```

## 6.13 syntax while

`<while.help>≡`

```
=====
while loops
=====
```

The repeat in a loop can be modified by adding one or more while clauses. Each clause contains a predicate immediately following the while keyword. The predicate is tested before the evaluation of the body of the loop. The loop body is evaluated whenever the predicate in a while clause is true.

The syntax for a simple loop using while is

```
while predicate repeat loopbody
```

The predicate is evaluated before loopbody is evaluated. A while loop terminates immediately when predicate evaluates to false or when a leave or return expression is evaluated. See `)help repeat` for more information on leave and return.

Here is a simple example of using while in a loop. We first initialize the counter.

```
i := 1
1
                                     Type: PositiveInteger

while i < 1 repeat
  output "hello"
  i := i + 1
                                     Type: Void
```

The steps involved in computing this example are

- (1) set i to 1
- (2) test the condition `i < 1` and determine that it is not true
- (3) do not evaluate the loop body and therefore do not display "hello"

```
(x, y) := (1, 1)
1
                                     Type: PositiveInteger
```

If you have multiple predicates to be tested use the logical and operation to separate them. Axiom evaluates these predicates from left to right.

```
while x < 4 and y < 10 repeat
  output [x,y]
  x := x + 1
  y := y + 2
[1,1]
[2,3]
[3,5]
```

Type: Void

A leave expression can be included in a loop body to terminate a loop even if the predicate in any while clauses are not false.

```
(x, y) := (1, 1)
1
```

Type: PositiveInteger

```
while x < 4 and y < 10 repeat
  if x + y > 7 then leave
  output [x,y]
  x := x + 1
  y := y + 2
[1,1]
[2,3]
```

Type: Void

## Chapter 7

# System Command Handling

### 7.0.1 defvar \$systemCommands

The system commands are the top-level commands available in Axiom that can all be invoked by prefixing the symbol with a closed-paren. Thus, to see they copyright you type:

```
)copyright
```

New commands need to be added to this table. The command invoked will be the first entry of the pair and the “user level” of the command will be the second entry.

See:

- The “abbreviations” (8.2.1 p 87) command
- The “boot” (9 p 91) command
- The “browse” (10 p 93) command
- The “cd” (11 p 99) command
- The “clear” (12.3.1 p 103) command
- The “close” (13.2.2 p 113) command
- The “compiler” (14.2.1 p 121) command
- The “copyright” (15.2.1 p 131) command
- The “credits” (16.3.1 p 133) command
- The “display” (17.2.1 p 137) command

- The “edit” (18.2.1 p 146) command
- The “fin” (19 p 149) command
- The “frame” (20.5.16 p 167) command
- The “help” (21.2.1 p 174) command
- The “history” (22.4.7 p 183) command
- The “lisp” (25 p 223) command
- The “library” (24 p 221) command
- The “load” (26 p 225) command
- The “ltrace” (27 p 227) command
- The “pquit” (28.2.1 p 230) command
- The “quit” (29.2.1 p 234) command
- The “read” (30 p 237) command
- The “savesystem” (31 p 239) command
- The “set” (32.40.1 p 372) command
- The “show” (33 p 377) command
- The “spool” (34 p 379) command
- The “summary” (35.1.1 p 382) command
- The “synonym” (36 p 383) command
- The “system” (37 p 385) command
- The “trace” (38.1.2 p 392) command
- The “undo” (39.3.2 p 450) command
- The “what” (40.1.2 p 467) command
- The “with” (41.1.1 p 473) command
- The “workfiles” (42.1.1 p 475) command
- The “zsystemdevelopment” (43.1.1 p 479) command

## 7.1 Variables Used

### 7.1.1 defvar \$systemCommands

$\langle initvars \rangle + \equiv$   
(defvar |\$systemCommands| nil)

```

<postvars> +=
(eval-when (eval load)
  (setq |$systemCommands|
    '(
      (|abbreviations|      . |compiler|    )
      (|boot|               . |development|)
      (|browse|             . |development|)
      (|cd|                 . |interpreter|)
      (|clear|              . |interpreter|)
      (|close|              . |interpreter|)
      (|compiler|           . |compiler|    )
      (|copyright|          . |interpreter|)
      (|credits|            . |interpreter|)
      (|display|            . |interpreter|)
      (|edit|               . |interpreter|)
      (|fin|                . |development|)
      (|frame|              . |interpreter|)
      (|help|               . |interpreter|)
      (|history|            . |interpreter|)
      ;; (|input|            . |interpreter|)
      (|lisp|               . |development|)
      (|library|            . |interpreter|)
      (|load|               . |interpreter|)
      (|ltrace|             . |interpreter|)
      (|pquit|              . |interpreter|)
      (|quit|               . |interpreter|)
      (|read|               . |interpreter|)
      (|savesystem|         . |interpreter|)
      (|set|                . |interpreter|)
      (|show|               . |interpreter|)
      (|spool|              . |interpreter|)
      (|summary|            . |interpreter|)
      (|synonym|            . |interpreter|)
      (|system|             . |interpreter|)
      (|trace|              . |interpreter|)
      (|undo|               . |interpreter|)
      (|what|               . |interpreter|)
      (|with|               . |interpreter|)
      (|workfiles|          . |development|)
      (|zsystemdevelopment| . |interpreter|)
    )))

```

**7.1.2 defvar \$syscommands**

This table is used to look up a symbol to see if it might be a command.

```
<initvars>+≡
  (defvar $syscommands nil)
```

```
<postvars>+≡
  (eval-when (eval load)
    (setq $syscommands (mapcar #'car |$systemCommands|)))
```

**7.1.3 defvar \$noParseCommands**

This is a list of the commands which have their arguments passed verbatim. Certain functions, such as the lisp function need to be able to handle all kinds of input that will not be acceptable to the interpreter.

```
<initvars>+≡
  (defvar |$noParseCommands| nil)
```

```
<postvars>+≡
  (eval-when (eval load)
    (setq |$noParseCommands|
      '(|boot| |copyright| |credits| |fin| |lisp| |pquit| |quit| |synonym| |system|
        )))
```

## 7.2 Functions

### 7.2.1 `defun handleNoParseCommands`

The system commands given by the global variable `$noParseCommands` require essentially no preprocessing/parsing of their arguments. Here we dispatch the functions which implement these commands.

There are four standard commands which receive arguments

- `boot`
- `lisp`
- `synonym`
- `system`

There are five standard commands which do not receive arguments –

- `quit`
- `fin`
- `pquit`
- `credits`
- `copyright`

As these commands do not necessarily exhaust those mentioned in `$noParseCommands`, we provide a generic dispatch based on two conventions: commands which do not require an argument name themselves, those which do have their names prefixed by “np”. This makes it possible to dynamically define new system commands provided you handle the argument parsing.

```
(defun handleNoParseCommands)≡
  (defun |handleNoParseCommands| (unab string)
    (let (spaceindex funname)
      (setq string (|stripSpaces| string))
      (setq spaceindex (search " " string))
      (cond
        ((eq unab '|lisp|)
         (if spaceindex
              (|nplisp| (|stripLisp| string))
              (|sayKeyedMsg| 's2iv0005 nil)))
        ((eq unab '|boot|)
         (if spaceindex
              (|npboot| (subseq string (1+ spaceindex)))
```

```

    (|sayKeyedMsg| 's2iv0005 nil)))
((eq unab '|system|)
 (if spaceindex
  (|npsystem| unab string)
  (|sayKeyedMsg| 's2iv0005 nil)))
((eq unab '|synonym|)
 (if spaceindex
  (|npsynonym| unab (subseq string (1+ spaceindex)))
  (|npsynonym| unab "")))
((null spaceindex)
 (funcall unab))
((|member| unab '(|quit| |fin| |pquit| |credits| |copyright|))
 (|sayKeyedMsg| 's2iv0005 nil))
(t
 (setq funname (intern (concat "np" (string unab))))
 (funcall funname (subseq string (1+ spaceindex))))))

```

### 7.2.2 defvar \$tokenCommands

This is a list of the commands that expect the interpreter to parse their arguments. Thus the history command expects that Axiom will have tokenized and validated the input before calling the history function.

```

<initvars>+≡
  (defvar |$tokenCommands| nil)

```

```

<postvars> +=
  (eval-when (eval load)
    (setq |$tokenCommands|
      '( |abbreviations|
        |cd|
        |clear|
        |close|
        |compiler|
        |depends|
        |display|
        |edit|
        |frame|
        |frame|
        |help|
        |history|
        |input|
        |library|
        |load|
        |ltrace|
        |read|
        |savesystem|
        |set|
        |spool|
        |undo|
        |what|
        |with|
        |workfiles|
        |zsystemdevelopment|
      )))

```

### 7.2.3 defvar \$InitialCommandSynonymAlist

Axiom can create “synonyms” for commands. We create an initial table of synonyms which are in common use.

```

<initvars> +=
  (defvar |$InitialCommandSynonymAlist| nil)

```

```

(postvars)+≡
(eval-when (eval load)
  (setq |$InitialCommandSynonymAlist|
    '(
      (|?|          . "what commands")
      (|ap|         . "what things")
      (|apr|        . "what things")
      (|apropos|    . "what things")
      (|cache|      . "set functions cache")
      (|cl|         . "clear")
      (|cls|        . "zsystemdevelopment )cls")
      (|cms|        . "system")
      (|co|         . "compiler")
      (|d|          . "display")
      (|dep|        . "display dependents")
      (|dependents| . "display dependents")
      (|e|          . "edit")
      (|expose|     . "set expose add constructor")
      (|fc|         . "zsystemdevelopment )c")
      (|fd|         . "zsystemdevelopment )d")
      (|fdt|        . "zsystemdevelopment )dt")
      (|fct|        . "zsystemdevelopment )ct")

(|wd|          . "what domains")
(|who|         . "lisp (pprint credits)")
(|wp|          . "what packages")
(|ws|          . "what synonyms")
)))

```

### 7.2.4 defvar \$CommandSynonymAlist

The actual list of synonyms is initialized to be the same as the above initial list of synonyms. The user synonyms that are added during a session are pushed onto this list for later lookup.

```

<initvars>+≡
  (defvar |$CommandSynonymAlist| nil)

<postvars>+≡
  (eval-when (eval load)
    (setq |$CommandSynonymAlist| (copy-alist |$InitialCommandSynonymAlist|)))

```

### 7.2.5 defun ncloopCommand

The \$systemCommandFunction is set in SpadInterpretStream to point to the function InterpExecuteSpadSystemCommand. The system commands are handled by the function kept in the “hook” variable \$systemCommandFunction which has the default function InterpExecuteSpadSystemCommand. Thus, when a system command is entered this function is called.

The only exception is the )include function which inserts the contents of a file inline in the input stream. This is useful for processing )read of input files.

```

<defun ncloopCommand>≡
  (defun |ncloopCommand| (line n)
    (let (a)
      (declare (special |$systemCommandFunction|))
      (if (setq a (|ncloopPrefix?| ")include" line))
          (|ncloopInclude1| a n)
          (progn
            (funcall |$systemCommandFunction| line)
            n))))

```

**7.2.6 defun ncloopPrefix?**

If we find the prefix string in the whole string starting at position zero we return the remainder of the string without the leading prefix.

```
<defun ncloopPrefix?>≡
  (defun |ncloopPrefix?| (prefix whole)
    (when (eql (search prefix whole) 0)
      (subseq whole (length prefix))))
```

**7.2.7 defun selectOptionLC**

```
<defun selectOptionLC>≡
  (defun |selectOptionLC| (x 1 errorFunction)
    (|selectOption| (downcase (|object2Identifier| x)) 1 errorFunction))
```

**7.2.8 defun selectOption**

```
<defun selectOption>≡
  (defun |selectOption| (x 1 errorfunction)
    (let (u y)
      (cond
        ((|member| x 1) x)
        ((null (identp x))
         (cond
          (errorfunction (funcall errorfunction x u))
          (t nil))))
      (t
       (setq u
              (let (t0)
                (do ((t1 1 (cdr t1)) (y nil))
                    ((or (atom t1) (progn (setq y (car t1)) nil)) (nreverse0 t0))
                  (if (|stringPrefix?| (pname x) (pname y))
                      (setq t0 (cons y t0)))))))
       (cond
        ((and (pairp u) (eq (qcdr u) nil) (progn (setq y (qcar u)) t)) y)
        (errorfunction (funcall errorfunction x u))
        (t nil))))))
```

## Chapter 8

# )abbreviations Command

### 8.1 abbreviations man page

*<abbreviations.help>*≡

```
=====
A.2. )abbreviation
=====
```

User Level Required: compiler

Command Syntax:

- )abbreviation query [nameOrAbbrev]
- )abbreviation category abbrev fullname [quiet]
- )abbreviation domain abbrev fullname [quiet]
- )abbreviation package abbrev fullname [quiet]
- )abbreviation remove nameOrAbbrev

Command Description:

This command is used to query, set and remove abbreviations for category, domain and package constructors. Every constructor must have a unique abbreviation. This abbreviation is part of the name of the subdirectory under which the components of the compiled constructor are stored. Furthermore, by issuing this command you let the system know what file to load automatically if you use a new constructor. Abbreviations must start with a letter and then be followed by up to seven letters or digits. Any letters appearing in the abbreviation must be in uppercase.

When used with the query argument, this command may be used to list the name

associated with a particular abbreviation or the abbreviation for a constructor. If no abbreviation or name is given, the names and corresponding abbreviations for all constructors are listed.

The following shows the abbreviation for the constructor List:

```
)abbreviation query List
```

The following shows the constructor name corresponding to the abbreviation NNI:

```
)abbreviation query NNI
```

The following lists all constructor names and their abbreviations.

```
)abbreviation query
```

To add an abbreviation for a constructor, use this command with category, domain or package. The following add abbreviations to the system for a category, domain and package, respectively:

```
)abbreviation domain SET Set
)abbreviation category COMPCAT ComplexCategory
)abbreviation package LIST2MAP ListToMap
```

If the )quiet option is used, no output is displayed from this command. You would normally only define an abbreviation in a library source file. If this command is issued for a constructor that has already been loaded, the constructor will be reloaded next time it is referenced. In particular, you can use this command to force the automatic reloading of constructors.

To remove an abbreviation, the remove argument is used. This is usually only used to correct a previous command that set an abbreviation for a constructor name. If, in fact, the abbreviation does exist, you are prompted for confirmation of the removal request. Either of the following commands will remove the abbreviation VECTOR2 and the constructor name VectorFunctions2 from the system:

```
)abbreviation remove VECTOR2
)abbreviation remove VectorFunctions2
```

Also See:

- o )compile

```

## Chapter 9

# )boot Command

### 9.1 boot man page

*<boot.help>*≡

=====

A.3. )boot

=====

User Level Required: development

Command Syntax:

- )boot bootExpression

Command Description:

This command is used by AXIOM system developers to execute expressions written in the BOOT language. For example,

)boot times3(x) == 3\*x

creates and compiles the Lisp function ‘times3’ obtained by translating the BOOT code.

Also See:

- o )fin
- o )lisp
- o )set
- o )system

## 9.2 Functions

This command is in the list of `$noParseCommands` 7.1.3 which means that its arguments are passed verbatim. This will eventually result in a call to the function `handleNoParseCommands` 7.2.1

---

<sup>1</sup> “fin” (19 p 149) “lisp” (25 p 223) “set” (32.40.1 p 372) “system” (37 p 385)

## Chapter 10

# )browse Command

### 10.1 browse man page

*<browse.help>*≡

User Level Required: development

Command Syntax:

)browse

Command Description:

This command is used by Axiom system users to start the Axiom top level loop listening for browser connections.

## 10.2 Overview

The Axiom book on the help browser is a complete rewrite of the hyperdoc mechanism. There are several components that were needed to make this function. Most of the web browser components are described in `bookvol11.pamphlet`. This portion describes some of the design issues needed to support the interface.

The `axServer` command takes a port (defaulting to 8085) and a program to handle the browser interaction (defaulting to `multiServ`). The `axServer` function opens the port, constructs the stream, and passes the stream to `multiServ`. The `multiServ` loop processes one interaction at a time.

So the basic process is that the Axiom “`)browse`” command opens a socket and listens for http requests. Based on the type of request (either ‘GET’ or ‘POST’) and the content of the request, which is one of:

- `command` - algebra request/response
- `lispcall` - a lisp s-expression to be evaluated
- `showcall` - an Axiom `)show` command

the `multiServ` function will call a handler function to evaluate the command line and construct a response. GET requests result in a new browser page. POST requests result in an inline result.

Most responses contain the fields:

- `stepnum` - this is the Axiom step number
- `command` - this is the original command from the browser
- `algebra` - this is the Axiom 2D algebra output
- `mathml` - this is the MathML version of the Axiom algebra
- `type` - this is the type of the Axiom result

## 10.3 Browsers, MathML, and Fonts

This work has the Firefox browser as its target. Firefox has built-in support for MathML, javascript, and XMLHttpRequest handling. More details are available in `bookvol11.pamphlet` but the very basic machinery for communication with the browser involves a dance between the browser and the `multiServ` function (see the `axserver.spad.pamphlet`).

In particular, a simple request is embedded in a web page as:

```

<ul>
  <li>
    <input type="submit" id="p3" class="subbut"
      onclick="makeRequest('p3');"
      value="sin(x)" />
    <div id="ansp3"><div></div></div>
  </li>
</ul>

```

which says that this is an html “input” field of type “submit”. The CSS display class is “subbut” which is of a different color than the surrounding text to make it obvious that you can click on this field. Clickable fields that have no response text are of class “noresult”.

The javascript call to “makeRequest” gives the “id” of this input field, which must be unique in the page, as an argument. In this case, the argument is ‘p3’. The “value” field holds the display text which will be passed back to Axiom as a command.

When the result arrives the “showanswer” function will select out the mathml field of the response, construct the “id” of the html div to hold the response by concatenating the string “ans” (answer) to the “id” of the request resulting, in this case, as “ansp3”. The “showanswer” function will find this div and replace it with a div containing the mathml result.

The “makeRequest” function is:

```

function makeRequest(arg) {
  http_request = new XMLHttpRequest();
  var command = commandline(arg);
  //alert(command);
  http_request.open('POST', '127.0.0.1:8085', true);
  http_request.onreadystatechange = handleResponse;
  http_request.setRequestHeader('Content-Type', 'text/plain');
  http_request.send("command="+command);
  return(false);
}

```

It contains a request to open a local server connection to Axiom, sets “handleResponse” as the function to call on reply, sets up the type of request, fills in the command field, and sends off the http request.

When a response is received, the “handleResponse” function checks for the correct reply state, strips out the important text, and calls “showanswer”.

```

function handleResponse() {
  if (http_request.readyState == 4) {
    if (http_request.status == 200) {
      showanswer(http_request.responseText, 'mathAns');
    } else
    {

```

```

        alert('There was a problem with the request.'+ http_request.statusText);
    }
}
}

```

See bookvol11.pamphlet for further details.

## 10.4 The axServer/multiServ loop

The basic call to start an Axiom browser listener is:

```

)set message autoload off
)set output mathml on
axServer(8085,multiServ)$AXSERV

```

This call sets the port, opens a socket, attaches it to a stream, and then calls “multiServ” with that stream. The “multiServ” function loops serving web responses to that port.

## 10.5 The )browse command

In order to make the whole process cleaner the function “)browse” handles the details. This code creates the command-line function for )browse

The browse function does the internal equivalent of the following 3 command line statments:

```

)set message autoload off
)set output mathml on
axServer(8085,multiServ)$AXSERV

```

which causes Axiom to start serving web pages on port 8085

For those unfamiliar with calling algebra from lisp there are a few points to mention.

The loadLib needs to be called to load the algebra code into the image. Normally this is automatic but we are not using the interpreter so we need to do this “by hand”.

Each algebra file contains a “constructor function” which builds the domain, which is a vector, and then caches the vector so that every call to the contructor returns an EQ vector, that is, the same vector. In this case, we call the constructor |AxiomServer|

The axServer function was mangled internally to |AXSERV;axServer;IMV;2|. The multiServ function was mangled to |AXSERV;multiServ;SeV;3| Note well

that if you change axserver.spad these names might change which will generate the error message along the lines of:

```
System error:
The function $\vert$AXSERV;axServer;IMV;2$\vert$ is undefined.
```

To fix this you need to look at int/algebra/AXSERV.nrlib/code.lsp and find the new mangled function name. A better solution would be to dynamically look up the surface names in the domain vector.

Each Axiom function expects the domain vector as the last argument. This is not obvious from the call as the interpreter supplies it. We must do that “by hand”.

We don’t call the multiServ function. We pass it as a parameter to the axServer function. When it does get called by the SPADCALL macro it needs to be a lisp pair whose car is the function and whose cdr is the domain vector. We construct that pair here as the second argument to axServer. The third, hidden, argument to axServer is the domain vector which we supply “by hand”.

The socket can be supplied on the command line but defaults to 8085. Axiom supplies the arguments as a list.

## 10.6 Variables Used

## 10.7 Functions

```
<defun browse>≡
(defun |browse| (socket)
  (let (axserv browser)
    (if socket
      (setq socket (car socket))
      (setq socket 8085))
    (|set| '(|mes| |auto| |off|))
    (|set| '(|out| |mathml| |on|))
    (|loadLib| '|AxiomServer|)
    (setq axserr (|AxiomServer|))
    (setq browser
      (|AXSERV;axServer;IMV;2| socket
        (cons #'|AXSERV;multiServ;SeV;3| axserr) axserr))))
```

Now we have to bolt it into Axiom. This involves two lookups.

We create the lisp pair

```
(|browse| . |development|)
```

and cons it into the `$systemCommands` command table. This allows the command to be executed in development mode. This lookup decides if this command is allowed. It also has the side-effect of putting the command into the `$SYSCOMMANDS` variable which is used to determine if the token is a command.

## 10.8 The server support code

# Chapter 11

## )cd Command

### 11.1 cd man page

`<cd.help>≡`

=====

A.4. )cd

=====

User Level Required: interpreter

Command Syntax:

- )cd directory

Command Description:

This command sets the AXIOM working current directory. The current directory is used for looking for input files (for )read), AXIOM library source files (for )compile), saved history environment files (for )history )restore), compiled AXIOM library files (for )library), and files to edit (for )edit). It is also used for writing spool files (via )spool), writing history input files (via )history )write) and history environment files (via )history )save), and compiled AXIOM library files (via )compile).

If issued with no argument, this command sets the AXIOM current directory to your home directory. If an argument is used, it must be a valid directory name. Except for the ‘)’ at the beginning of the command, this has the same syntax as the operating system cd command.

Also See:

- o )compile
- o )edit
- o )history
- o )library
- o )read
- o )spool

1

## 11.2 Variables Used

## 11.3 Functions

---

<sup>1</sup> “compile” (?? p ??) “edit” (18.2.1 p 146) “history” (22.4.7 p 183) “library” (24 p 221) “read” (30 p 237) “spool” (34 p 379)

## Chapter 12

# )clear Command

### 12.1 clear man page

`<clear.help>≡`

```
=====
A.6.  )clear
=====
```

User Level Required: interpreter

Command Syntax:

```
- )clear all
- )clear completely
- )clear properties all
- )clear properties  obj1 [obj2 ...]
- )clear value      all
- )clear value      obj1 [obj2 ...]
- )clear mode       all
- )clear mode       obj1 [obj2 ...]
```

Command Description:

This command is used to remove function and variable declarations, definitions and values from the workspace. To empty the entire workspace and reset the step counter to 1, issue

```
)clear all
```

To remove everything in the workspace but not reset the step counter, issue

```
)clear properties all
```

To remove everything about the object `x`, issue

```
)clear properties x
```

To remove everything about the objects `x`, `y` and `f`, issue

```
)clear properties x y f
```

The word `properties` may be abbreviated to the single letter `'p'`.

```
)clear p all
```

```
)clear p x
```

```
)clear p x y f
```

All definitions of functions and values of variables may be removed by either

```
)clear value all
```

```
)clear v all
```

This retains whatever declarations the objects had. To remove definitions and values for the specific objects `x`, `y` and `f`, issue

```
)clear value x y f
```

```
)clear v x y f
```

To remove the declarations of everything while leaving the definitions and values, issue

```
)clear mode all
```

```
)clear m all
```

To remove declarations for the specific objects `x`, `y` and `f`, issue

```
)clear mode x y f
```

```
)clear m x y f
```

The `)display names` and `)display properties` commands may be used to see what is currently in the workspace.

The command

```
)clear completely
```

does everything that `)clear` all does, and also clears the internal system function and constructor caches.

Also See:

- o `)display`
- o `)history`
- o `)undo`

<sup>1</sup>

## 12.2 Variables Used

### 12.2.1 `defvar $clearOptions`

## Chapter 13

# )close Command

### 13.1 close man page

`<close.help>≡`

=====

A.5. )close

=====

User Level Required: interpreter

Command Syntax:

- )close
- )close )quietly

Command Description:

This command is used to close down interpreter client processes. Such processes are started by HyperDoc to run AXIOM examples when you click on their text. When you have finished examining or modifying the example and you do not want the extra window around anymore, issue

)close

to the AXIOM prompt in the window.

If you try to close down the last remaining interpreter client process, AXIOM will offer to close down the entire AXIOM session and return you to the operating system by displaying something like

This is the last AXIOM session. Do you want to kill AXIOM?

Type "y" (followed by the Return key) if this is what you had in mind. Type "n" (followed by the Return key) to cancel the command.

You can use the )quietly option to force AXIOM to close down the interpreter client process without closing down the entire AXIOM session.

Also See:

- o )quit
- o )pquit

- )compile fileName )break
- )compile fileName )nobreak
- )compile fileName )library
- )compile fileName )nolibrary
- )compile fileName )vartrace
- )compile fileName )constructor nameOrAbbrev

```

#### Command Description:

You use this command to invoke the new AXIOM library compiler or the old AXIOM system compiler. The `)compile` system command is actually a combination of AXIOM processing and a call to the AXIOM-XL compiler. It is performing double-duty, acting as a front-end to both the AXIOM-XL compiler and the old AXIOM system compiler. (The old AXIOM system compiler was written in Lisp and was an integral part of the AXIOM environment. The AXIOM-XL compiler is written in C and executed by the operating system when called from within AXIOM.)

The command compiles files with file extensions `.as`, `.ao` and `.al` with the AXIOM-XL compiler and files with file extension `.spad` with the old AXIOM system compiler. It also can compile files with file extension `.lsp`. These are assumed to be Lisp files generated by the AXIOM-XL compiler. If you omit the file extension, the command looks to see if you have specified the `)new` or `)old` option. If you have given one of these options, the corresponding compiler is used. Otherwise, the command first looks in the standard system directories for files with extension `.as`, `.ao` and `.al` and then files with extension `.spad`. The first file found has the appropriate compiler invoked on it. If the command cannot find a matching file, an error message is displayed and the command terminates.

The `)translate` option is used to invoke a special version of the old system compiler that will translate a `.spad` file to a `.as` file. That is, the `.spad` file will be parsed and analyzed and a file using the new syntax will be created. By default, the `.as` file is created in the same directory as the `.spad` file. If that directory is not writable, the current directory is used. If the current directory is not writable, an error message is given and the command terminates. Note that `)translate` implies the `)old` option so the file extension can safely be omitted. If `)translate` is given, all other options are ignored. Please be aware that the translation is not necessarily one hundred percent complete or correct. You should attempt to compile the output with the AXIOM-XL compiler and make any necessary corrections.

We now describe the options for the new AXIOM-XL compiler.

The first thing `)compile` does is look for a source code filename among its

arguments. Thus

```
)compile mycode.as
)compile /u/jones/as/mycode.as
)compile mycode
```

all invoke `)compiler` on the file `/u/jones/as/mycode.as` if the current AXIOM working directory is `/u/jones/as`. (Recall that you can set the working directory via the `)cd` command. If you don't set it explicitly, it is the directory from which you started AXIOM.)

This is frequently all you need to compile your file. This simple command:

- Invokes the AXIOM-XL compiler and produces Lisp output.
- Calls the Lisp compiler if the AXIOM-XL compilation was successful.
- Use the `)library` command to tell AXIOM about the contents of your compiled file and arrange to have those contents loaded on demand.

Should you not want the `)library` command automatically invoked, call `)compile` with the `)nolibrary` option. For example,

```
)compile mycode.as )nolibrary
```

The general description of AXIOM-XL command line arguments is in the AXIOM-XL documentation. The default options used by the `)compile` command can be viewed and set using the `)set compiler args AXIOM` system command. The current defaults are

```
-O -Fasy -Fao -Flsp -laxiom -Mno-AXL_WillObsolete -DAxiom
```

These options mean:

- `-O`: perform all optimizations,
- `-Fasy`: generate a `.asy` file,
- `-Fao`: generate a `.ao` file,
- `-Flsp`: generate a `.lsp` (Lisp) file,
- `-laxiom`: use the axiom library `libaxiom.al`,
- `-Mno-AXL_WillObsolete`: do not display messages about older generated files becoming obsolete, and
- `-DAxiom`: define the global assertion `Axiom` so that the AXIOM-XL libraries for generating stand-alone code are not accidentally used with AXIOM.

To supplement these default arguments, use the `)moreargs` option on `)compile`. For example,

```
)compile mycode.as )moreargs "-v"
```

uses the default arguments and appends the `-v` (verbose) argument flag. The additional argument specification must be enclosed in double quotes.

To completely replace these default arguments for a particular use of `)compile`, use the `)onlyargs` option. For example,

```
)compile mycode.as )onlyargs "-v -O"
```

only uses the `-v` (verbose) and `-O` (optimize) arguments. The argument specification must be enclosed in double quotes. In this example, Lisp code is not produced and so the compilation output will not be available to AXIOM.

To completely replace the default arguments for all calls to `)compile` within your AXIOM session, use `)set compiler args`. For example, to use the above arguments for all compilations, issue

```
)set compiler args "-v -O"
```

Make sure you include the necessary `-l` and `-Y` arguments along with those needed for Lisp file creation. As above, the argument specification must be enclosed in double quotes.

By default, the `)library` system command exposes all domains and categories it processes. This means that the AXIOM interpreter will consider those domains and categories when it is trying to resolve a reference to a function. Sometimes domains and categories should not be exposed. For example, a domain may just be used privately by another domain and may not be meant for top-level use. The `)library` command should still be used, though, so that the code will be loaded on demand. In this case, you should use the `)nolibary` option on `)compile` and the `)noexpose` option in the `)library` command. For example,

```
)compile mycode.as )nolibary
)library mycode )noexpose
```

Once you have established your own collection of compiled code, you may find it handy to use the `)dir` option on the `)library` command. This causes `)library` to process all compiled code in the specified directory. For example,

```
)library )dir /u/jones/as/quantum
```

You must give an explicit directory after `)dir`, even if you want all compiled code in the current working directory processed.

```
)library )dir .
```

The `)compile` command works with several file extensions. We saw above what happens when it is invoked on a file with extension `.as`. A `.ao` file is a portable binary compiled version of a `.as` file, and `)compile` simply passes the `.ao` file onto AXIOM-XL. The generated Lisp file is compiled and `)library` is automatically called, just as if you had specified a `.as` file.

A `.al` file is an archive file containing `.ao` files. The archive is created (on Unix systems) with the `ar` program. When `)compile` is given a `.al` file, it creates a directory whose name is based on that of the archive. For example, if you issue

```
)compile mylib.al
```

the directory `mylib.axldir` is created. All members of the archive are unarchived into the directory and `)compile` is called on each `.ao` file found. It is your responsibility to remove the directory and its contents, if you choose to do so.

A `.lsp` file is a Lisp source file, presumably, in our context, generated by AXIOM-XL when called with the `-Flsp` option. When `)compile` is used with a `.lsp` file, the Lisp file is compiled and `)library` is called. You must also have present a `.asy` generated from the same source file.

The following are descriptions of options for the old system compiler.

You can compile category, domain, and package constructors contained in files with file extension `.spad`. You can compile individual constructors or every constructor in a file.

The full filename is remembered between invocations of this command and `)edit` commands. The sequence of commands

```
)compile matrix.spad
)edit
)compile
```

will call the compiler, edit, and then call the compiler again on the file `matrix.spad`. If you do not specify a directory, the working current directory (see description of command `)cd`) is searched for the file. If the file is not found, the standard system directories are searched.

If you do not give any options, all constructors within a file are compiled. Each constructor should have an `)abbreviation` command in the file in which it is defined. We suggest that you place the `)abbreviation` commands at the top of the file in the order in which the constructors are defined. The list of commands serves as a table of contents for the file.

The `)library` option causes directories containing the compiled code for each constructor to be created in the working current directory. The name of such a directory consists of the constructor abbreviation and the `.NRLIB` file extension. For example, the directory containing the compiled code for the `MATRIX` constructor is called `MATRIX.NRLIB`. The `)nolibrary` option says that such files should not be created. The default is `)library`. Note that the semantics of `)library` and `)nolibrary` for the new AXIOM-XL compiler and for the old system compiler are completely different.

The `)vartrace` option causes the compiler to generate extra code for the constructor to support conditional tracing of variable assignments. (see description of command `)trace`). Without this option, this code is suppressed and one cannot use the `)vars` option for the `trace` command.

The `)constructor` option is used to specify a particular constructor to compile. All other constructors in the file are ignored. The constructor name or abbreviation follows `)constructor`. Thus either

```
)compile matrix.spad )constructor RectangularMatrix
```

or

```
)compile matrix.spad )constructor RMATRIX
```

compiles the `RectangularMatrix` constructor defined in `matrix.spad`.

The `)break` and `)nobreak` options determine what the old system compiler does when it encounters an error. `)break` is the default and it indicates that processing should stop at the first error. The value of the `)set break` variable then controls what happens.

## 15.2 Functions

### 15.2.1 defun copyright

```
<defun copyright>≡  
  (defun |copyright| ()  
    (obey (strconc "cat " (getenv "AXIOM") "/doc/spadhelp/spadhelp.help")))
```

This command is in the list of `$noParseCommands` 7.1.3 which means that its arguments are passed verbatim. This will eventually result in a call to the function `handleNoParseCommands` 7.2.1

## Chapter 16

# )credits Command

### 16.1 credits man page

### 16.2 Variables Used

### 16.3 Functions

#### 16.3.1 defun credits

```
<defun credits>≡  
  (defun |credits| ()  
    (declare (special credits))  
    (mapcar #'(lambda (x) (princ x) (terpri)) credits))
```

This command is in the list of `$noParseCommands` 7.1.3 which means that its arguments are passed verbatim. This will eventually result in a call to the function `handleNoParseCommands` 7.2.1

## Chapter 17

# )display Command

### 17.1 display man page

*<display.help>*≡

=====

A.8. )display

=====

User Level Required: interpreter

Command Syntax:

- )display all
- )display properties
- )display properties all
- )display properties [obj1 [obj2 ...]]
- )display value all
- )display value [obj1 [obj2 ...]]
- )display mode all
- )display mode [obj1 [obj2 ...]]
- )display names
- )display operations opName

Command Description:

This command is used to display the contents of the workspace and signatures of functions with a given name. (A signature gives the argument and return types of a function.)

The command

)display names

lists the names of all user-defined objects in the workspace. This is useful if you do not wish to see everything about the objects and need only be reminded of their names.

The commands

)display all  
)display properties  
)display properties all

all do the same thing: show the values and types and declared modes of all variables in the workspace. If you have defined functions, their signatures and definitions will also be displayed.

To show all information about a particular variable or user functions, for example, something named `d`, issue

)display properties `d`

To just show the value (and the type) of `d`, issue

)display value `d`

To just show the declared mode of `d`, issue

)display mode `d`

All modemaps for a given operation may be displayed by using `)display` operations. A modemap is a collection of information about a particular reference to an operation. This includes the types of the arguments and the return value, the location of the implementation and any conditions on the types. The modemap may contain patterns. The following displays the modemaps for the operation `FromcomplexComplexCategory`:

)d op complex

Also See:

- o )clear
- o )history
- o )set
- o )show
- o )what

1

### 17.1.1 defvar \$displayOptions

The current value of \$displayOptions is

```
<initvars>+≡
  (defvar |$displayOptions|
    '(|abbreviations| |all| |macros| |modes| |names| |operations|
      |properties| |types| |values|))
```

## 17.2 Functions

### 17.2.1 defun display

This trivial function satisfies the standard pattern of making a user command match the name of the function which implements the command. That command immediatly invokes a “Spad2Cmd” version.

```
<defun display>≡
  (defun |display| (l)
    (displaySpad2Cmd l))
```

---

<sup>1</sup> “clear” (12.3.1 p 103) “history” (22.4.7 p 183) “set” (32.40.1 p 372) “show” (33 p 377) “what” (40.1.2 p 467)

### 17.2.2 displaySpad2Cmd

We process the options to the command and call the appropriate display function. There are really only 4 display functions. All of the other options are just subcases.

There is a slight mismatch between the \$displayOptions list of symbols and the options this command accepts so we have a cond branch to clean up the option variable. This allows for the options to be plural.

If we fall all the way thru we use the \$displayOptions list to construct a list of strings for the sayMessage function and tell the user what options are available.

```
(defun displaySpad2Cmd)≡
  (defun displaySpad2Cmd (l)
    (let ((|$e| |$EmptyEnvironment|) (opt (car l)) (vl (cdr l)) option)
      (declare (special |$e| |$EmptyEnvironment| |$displayOptions|))
      (if (and (pairp l) (not (eq opt '?)))
        (progn
          (setq option (|selectOptionLC| opt |$displayOptions| '|optionError|))
          (cond
            ((eq option '|all|)
              (setq l (list '|properties|))
              (setq option '|properties|))
            ((or (eq option '|modes|) (eq option '|types|))
              (setq l (cons '|type| vl))
              (setq option '|type|))
            ((eq option '|values|)
              (setq l (cons '|value| vl))
              (setq option '|value|)))
          (cond
            ((eq option '|abbreviations|)
              (if (null vl)
                (|listConstructorAbbreviations|)
                (dolist (v vl) (|abbQuery| (|opOf| v))))))
            ((eq option '|operations|) (|displayOperations| vl))
            ((eq option '|macros|) (|displayMacros| vl))
            ((eq option '|names|) (|displayWorkspaceNames|))
            (t (|displayProperties| option l))))
        (|sayMessage|
          (append
            '(" )display keyword arguments are")
            (mapcar #'(lambda (x) (format nil "~%      ~a" x)) |$displayOptions|)
            (format nil "~% or abbreviations thereof"))))))))
```

**17.2.3 defun abbQuery**

```

⟨defun abbQuery⟩≡
  (defun |abbQuery| (x)
    (let (abb)
      (cond
        ((setq abb (getdatabase x 'abbreviation))
         (|sayKeyedMsg| 's2iz0001 (list abb (getdatabase x 'constructorkind) x)))
        ((setq abb (getdatabase x 'constructor))
         (|sayKeyedMsg| 's2iz0001 (list x (getdatabase abb 'constructorkind) abb)))
        (t
         (|sayKeyedMsg| 's2iz0003 (list x)))))))

```

**17.2.4 defun displayOperations**

This function takes a list of operation names. If the list is null we query the user to see if they want all operations printed. Otherwise we print the information for the requested symbols.

```

⟨defun displayOperations⟩≡
  (defun |displayOperations| (l)
    (if l
        (dolist (op l) (|reportOpSymbol| op))
        (if (yesanswer)
            (dolist (op (|allOperations|)) (|reportOpSymbol| op))
            (|sayKeyedMsg| 's2iz0059 nil))))

```

**17.2.5 defun yesanswer**

This is a trivial function to simplify the logic of displaySpad2Cmd. If the user didn't supply an argument to the )display op command we ask if they wish to have all information about all Axiom operations displayed. If the answer is either Y or YES we return true else nil.

```

⟨defun yesanswer⟩≡
  (defun yesanswer ()
    (memq (string2id-n (upcase (|queryUserKeyedMsg| 's2iz0058 nil)) 1) '(y yes)))

```

### 17.2.6 defun displayMacros

```

(defun displayMacros)≡
  (defun |displayMacros| (names)
    (let (imacs pmacs macros first)
      (setq imacs (|getInterpMacroNames|))
      (setq pmacs (|getParserMacroNames|))
      (if names
        (setq macros names)
        (setq macros (append imacs pmacs)))
      (setq macros (remdup macros))
      (cond
        ((null macros) (|sayBrightly| "  There are no Axiom macros."))
        (t
         (setq first t)
         (do ((t0 macros (cdr t0)) (macro nil))
             ((or (atom t0) (progn (setq macro (car t0)) nil)) nil)
          (seq
           (exit
            (cond
              ((|member| macro pmacs)
               (cond
                (first (|sayBrightly|
                        (cons '|%l| (cons "User-defined macros:" nil))) (setq first nil)))
                (|displayParserMacro| macro))
              ((|member| macro imacs) '|iterate|)
              (t (|sayBrightly|
                  (cons "  "
                     (cons '|%b|
                        (cons macro
                           (cons '|%d| (cons " is not a known Axiom macro." nil))))))))))
          (setq first t)
          (do ((t1 macros (cdr t1)) (macro nil))
              ((or (atom t1) (progn (setq macro (car t1)) nil)) nil)
            (seq
             (exit
              (cond
                ((|member| macro imacs)
                 (cond
                  ((|member| macro pmacs) '|iterate|)
                  (t
                   (cond
                    (first
                     (|sayBrightly|
                      (cons '|%l|
                         (cons "System-defined macros:" nil))) (setq first nil)))

```

```
      (|displayMacro| macro)))  
    ((|member| macro pmacs) '|iterate|)))))  
  nil)))
```

### 17.2.7 defun sayExample

This function expects 2 arguments, the documentation string and the name of the operation. It searches the documentation string for `++X` lines. These lines are examples lines for functions. They look like ordinary `++` comments and fit into the ordinary comment blocks. So, for example, in the `plot.spad.pamphlet` file we find the following function signature:

```
plot: (F -> F,R) -> %
++ plot(f,a..b) plots the function \spad{f(x)}
++ on the interval \spad{[a,b]}.
++
++X fp:=(t:DFLOAT):DFLOAT --> sin(t)
++X plot(fp,-1.0..1.0)$PLOT
```

This function splits out and prints the lines that begin with `++X`.

A minor complication of printing the examples is that the lines have been processed into internal compiler format. Thus the lines that read:

```
++X fp:=(t:DFLOAT):DFLOAT --> sin(t)
++X plot(fp,-1.0..1.0)$PLOT
```

are actually stored as one long line containing the example lines

```
"\\indented{1}{plot(\\spad{f},{a..\\spad{b}}) plots the function
\\spad{f(x)} \\indented{1}{on the interval \\spad{[a,{b}]}.)}
\\blankline
\\spad{X} fp:=(t:DFLOAT):DFLOAT --> sin(\\spad{t})
\\spad{X} plot(\\spad{fp},{\\spad{-1}.0..1.0)}\\$PLOT"
```

So when we have an example line starting with `++X`, it gets converted to the compiler to `\spad{X}`. So each example line is delimited by `\spad{X}`.

The compiler also removes the newlines so if there is a subsequent `\spad{X}` in the docstring then it implies multiple example lines and we loop over them, splitting them up at the delimiter.

If there is only one then we clean it up and print it.

```
<defun sayExample>≡
(defun sayExample (docstring)
  (let (line point)
    (when (setq point (search "spad{X}" docstring))
      (setq line (subseq docstring (+ point 8)))
      (do ((mark (search "spad{X}" line) (search "spad{X}" line)))
          ((null mark))
          (princ (cleanupLine (subseq line 0 mark)))
          (|sayNewLine|)
          (setq line (subseq line (+ mark 8)))))))
```

```
(princ (cleanupLine line))
(|sayNewLine|)
(|sayNewLine|)))
```

### 17.2.8 defun cleanupLine

This function expects example lines in internal format that has been partially processed to remove the prefix. Thus we get lines that look like:

```
fp:=(t:DFLOAT):DFLOAT +-> sin(\spad{t})
plot(\spad{fp},{}\spad{-1}.0..1.0)\$PLOT
```

It removes all instances of {}, and \, and unwraps the `spad{}` call, leaving only the argument.

We return lines that look like:

```
fp:=(t:DFLOAT):DFLOAT +-> sin(t)
plot(fp,-1.0..1.0)$PLOT
```

which is hopefully exactly what the user wrote.

The compiler inserts {} as a space so we remove it. We remove all of the \ characters. We remove all of the `spad{...}` delimiters which will occur around other `spad` variables. Technically we should search recursively for the matching delimiter rather than the next brace but the problem does not arise in practice.

```
<defun cleanupLine>=
(defun cleanupLine (line)
  (do ((mark (search "{}" line) (search "{}" line)))
      ((null mark))
      (setq line
        (concatenate 'string (subseq line 0 mark) (subseq line (+ mark 2))))))
  (do ((mark (search "\\\" line) (search "\\\" line)))
      ((null mark))
      (setq line
        (concatenate 'string (subseq line 0 mark) (subseq line (+ mark 1))))))
  (do ((mark (search "spad{" line) (search "spad{" line)))
      ((null mark))
      (let (left point mid right)
        (setq left (subseq line 0 mark))
        (setq point (search "}" line :start2 mark))
        (setq mid (subseq line (+ mark 5) point))
        (setq right (subseq line (+ point 1)))
        (setq line (concatenate 'string left mid right))))
    line)
```

## Chapter 18

# )edit Command

### 18.1 edit man page

*<edit.help>*≡

```
=====
A.9.  )edit
=====
```

User Level Required: interpreter

Command Syntax:

```
- )edit [filename]
```

Command Description:

This command is used to edit files. It works in conjunction with the `)read` and `)compile` commands to remember the name of the file on which you are working. By specifying the name fully, you can edit any file you wish. Thus

```
)edit /u/julius/matrix.input
```

will place you in an editor looking at the file `/u/julius/matrix.input`. By default, the editor is `vi`, but if you have an `EDITOR` shell environment variable defined, that editor will be used. When AXIOM is running under the X Window System, it will try to open a separate `xterm` running your editor if it thinks one is necessary. For example, under the Korn shell, if you issue

```
export EDITOR=emacs
```

then the emacs editor will be used by `)edit`.

If you do not specify a file name, the last file you edited, read or compiled will be used. If there is no ‘‘last file’’ you will be placed in the editor editing an empty unnamed file.

It is possible to use the `)system` command to edit a file directly. For example,

```
)system emacs /etc/rc.tcpip
```

calls emacs to edit the file.

Also See:

- o `)system`
- o `)compile`
- o `)read`

1

## 18.2 Functions

### 18.2.1 `defun edit`

```
<defun edit>≡
  (defun |edit| (1) (|editSpad2Cmd| 1))
```

---

<sup>1</sup> “system” (37 p 385) “compile” (?? p ??) “read” (30 p 237)

**18.2.2 defun editSpad2Cmd**

```

<defun editSpad2Cmd>≡
  (defun |editSpad2Cmd| (l)
    (let (olddir filetypes ll rc)
      (declare (special /editfile))
      (setq l (cond ((null l) /editfile) (t (car l))))
      (setq l (|pathname| l))
      (setq olddir (|pathnameDirectory| l))
      (setq filetypes
        (cond
          ((|pathnameType| l) (list (|pathnameType| l)))
          ((eq |$UserLevel| '|interpreter|) '("input" "INPUT" "spad" "SPAD"))
          ((eq |$UserLevel| '|compiler|) '("input" "INPUT" "spad" "SPAD"))
          (t '("input" "INPUT" "spad" "SPAD" "boot" "BOOT"
              "lisp" "LISP" "meta" "META"))))
      (setq ll
        (cond
          ((string= olddir "")
            (|pathname| ($findfile (|pathnameName| l) filetypes)))
          (t l)))
      (setq l (|pathname| ll))
      (setq /editfile l)
      (setq rc (|editFile| l))
      (|updateSourceFiles| l)
      rc))

```

## Chapter 19

# )fin Command

### 19.1 fin man page

*<fin.help>*≡

=====

A.10. )fin

=====

User Level Required: development

Command Syntax:

- )fin

Command Description:

This command is used by AXIOM developers to leave the AXIOM system and return to the underlying Lisp system. To return to AXIOM, issue the ‘‘(|spad|)’’ function call to Lisp.

Also See:

- o )pquit
- o )quit

## 19.2 Functions

This command is in the list of `$noParseCommands` 7.1.3 which means that its arguments are passed verbatim. This will eventually result in a call to the function `handleNoParseCommands` 7.2.1

---

<sup>1</sup> “pquit” (28.2.1 p 230) “quit” (29.2.1 p 234)

## Chapter 20

# )frame Command

### 20.1 frame man page

`<frame.help>`≡

```
=====
A.11.  )frame
=====
```

User Level Required: interpreter

Command Syntax:

```
- )frame new frameName
- )frame drop [frameName]
- )frame next
- )frame last
- )frame names
- )frame import frameName [objectName1 [objectName2 ...]]
- )set message frame on | off
- )set message prompt frame
```

Command Description:

A frame can be thought of as a logical session within the physical session that you get when you start the system. You can have as many frames as you want, within the limits of your computer's storage, paging space, and so on. Each frame has its own step number, environment and history. You can have a variable named `a` in one frame and it will have nothing to do with anything that might be called `a` in any other frame.

Some frames are created by the HyperDoc program and these can have pretty strange names, since they are generated automatically. To find out the names of all frames, issue

```
)frame names
```

It will indicate the name of the current frame.

You create a new frame ‘‘quark’’ by issuing

```
)frame new quark
```

The history facility can be turned on by issuing either `)set history on` or `)history on`. If the history facility is on and you are saving history information in a file rather than in the AXIOM environment then a history file with filename `quark.axh` will be created as you enter commands. If you wish to go back to what you were doing in the ‘‘initial’’ frame, use

```
)frame next
```

or

```
)frame last
```

to cycle through the ring of available frames to get back to ‘‘initial’’.

If you want to throw away a frame (say ‘‘quark’’), issue

```
)frame drop quark
```

If you omit the name, the current frame is dropped.

If you do use frames with the history facility on and writing to a file, you may want to delete some of the older history files. These are directories, so you may want to issue a command like `rm -r quark.axh` to the operating system.

You can bring things from another frame by using `)frame import`. For example, to bring the `f` and `g` from the frame ‘‘quark’’ to the current frame, issue

```
)frame import quark f g
```

If you want everything from the frame ‘‘quark’’, issue

```
)frame import quark
```

You will be asked to verify that you really want everything.

There are two `)set` flags to make it easier to tell where you are.

`)set message frame on | off`

will print more messages about frames when it is set on. By default, it is off.

`)set message prompt frame`

will give a prompt that looks like

initial (1) ->

when you start up. In this case, the frame name and step make up the prompt.

Also See:

- o `)history`
- o `)set`

## 20.2 Variables Used

The frame mechanism uses several dollar variables.

### 20.2.1 Primary variables

Primary variables are those which exist solely to make the frame mechanism work.

The `$interpreterFrameName` contains a symbol which is the name of the current frame in use.

The `$interpreterFrameRing` contains a list of all of the existing frames. The first frame on the list is the “current” frame. When AXIOMsys is started directly there is only one frame named “initial”.

If the system is started under sman (using the axiom shell script, for example), there are two frames, “initial” and “frame0”. In this case, “frame0” is the current frame. This can cause subtle problems because functions defined in the axiom initialization file (`.axiom.input`) will be defined in frame “initial” but the current frame will be “frame0”. They will appear to be undefined. However, if the user does “`)frame next`” they can switch to the “initial” frame and see the functions correctly defined.

The `$frameMessages` variable controls when frame messages will be displayed. The variable is initially NIL. It can be set on (T) or off (NIL) using the system command:

```
)set message frame on | off
```

Setting frame messages on will output a line detailing the current frame after every output is complete.

### 20.2.2 Used variables

The frame collects and uses a few top level variables. These are: `$InteractiveFrame`, `$IOindex`, `$HiFiAccess`, `$HistList`, `$HistListLen`, `$HistListAct`, `$HistRecord`, `$internalHistoryTable`, and `$localExposureData`.

These variables can also be changed by the frame mechanism when the user requests changing to a different frame.

---

<sup>1</sup> “history” (22.4.7 p 183) “set” (32.40.1 p 372)

## 20.3 Data Structures

### 20.3.1 Frames and the Interpreter Frame Ring

Axiom has the notion of “frames”. A frame is a data structure which holds all the vital data from an Axiom session. There can be multiple frames and these live in a top-level variable called `$interpreterFrameRing`. This variable holds a circular list of frames. The parts of a frame and their initial, default values are:

<code>\$interpreterFrameName</code>	a string, named on creation
<code>\$InteractiveFrame</code>	(list (list nil))
<code>\$IOindex</code>	an integer, 1
<code>\$HiFiAccess</code>	<code>\$HiFiAccess</code> , see the variable description
<code>\$HistList</code>	<code>\$HistList</code> , see the variable description
<code>\$HistListLen</code>	<code>\$HistListLen</code> , see the variable description
<code>\$HistListAct</code>	<code>\$HistListAct</code> , see the variable description
<code>\$HistRecord</code>	<code>\$HistRecord</code> , see the variable description
<code>\$internalHistoryTable</code>	nil
<code>\$localExposureData</code>	a copy of <code>\$localExposureData</code>

## 20.4 Accessor Functions

These could be macros but we wish to export them to the API code in the algebra so we keep them as functions.

### 20.4.1 0th Frame Component – `frameName`

#### 20.4.2 `defun frameName`

```
<defun frameName>≡
  (defun frameName (frame)
    (car frame))
```

### 20.4.3 1st Frame Component – `frameInteractive`

```
<defun frameInteractive>≡
  (defun frameInteractive (frame)
    (nth 1 frame))
```

#### 20.4.4 2nd Frame Component – frameIOIndex

```
<defun frameIOIndex>≡  
  (defun frameIOIndex (frame)  
    (nth 2 frame))
```

#### 20.4.5 3rd Frame Component – frameHiFiAccess

```
<defun frameHiFiAccess>≡  
  (defun frameHiFiAccess (frame)  
    (nth 3 frame))
```

#### 20.4.6 4th Frame Component – frameHistList

```
<defun frameHistList>≡  
  (defun frameHistList (frame)  
    (nth 4 frame))
```

#### 20.4.7 5th Frame Component – frameHistListLen

```
<defun frameHistListLen>≡  
  (defun frameHistListLen (frame)  
    (nth 5 frame))
```

#### 20.4.8 6th Frame Component – frameHistListAct

```
<defun frameHistListAct>≡  
  (defun frameHistListAct (frame)  
    (nth 6 frame))
```

#### 20.4.9 7th Frame Component – frameHistRecord

```
<defun frameHistRecord>≡  
  (defun frameHistRecord (frame)  
    (nth 7 frame))
```

**20.4.10 8th Frame Component – frameHistoryTable**

```

<defun frameHistoryTable>≡
  (defun frameHistoryTable (frame)
    (nth 8 frame))

```

**20.4.11 9th Frame Component – frameExposureData**

```

<defun frameExposureData>≡
  (defun frameExposureData (frame)
    (nth 9 frame))

```

**20.5 Functions****20.5.1 Initializing the Interpreter Frame Ring**

Now that we know what a frame looks like we need a function to initialize the list of frames. This function sets the initial frame name to “initial” and creates a list of frames containing an empty frame. This list is the interpreter frame ring and is not actually circular but is managed as a circular list.

As a final step we update the world from this frame. This has the side-effect of resetting all the important global variables to their initial values.

```

<defun initializeInterpreterFrameRing>≡
  (defun |initializeInterpreterFrameRing| ()
    "Initializing the Interpreter Frame Ring"
    (declare (special |$interpreterFrameName| |$interpreterFrameRing|))
    (setq |$interpreterFrameName| '|initial|)
    (setq |$interpreterFrameRing|
      (list (|emptyInterpreterFrame| |$interpreterFrameName|)))
    (|updateFromCurrentInterpreterFrame|)
    nil)

```

### 20.5.2 Creating a List of all of the Frame Names

This function simply walks across the frame in the frame ring and returns a list of the name of each frame.

```
<defun frameNames>≡
  (defun |frameNames| ()
    "Creating a List of all of the Frame Names"
    (declare (special |$interpreterFrameRing|))
    (mapcar #'frameName |$interpreterFrameRing|))
```

### 20.5.3 Get Named Frame Environment (aka Interactive)

If the frame is found we return the environment portion of the frame otherwise we construct an empty environment and return it. The initial values of an empty frame are created here. This function returns a single frame that will be placed in the frame ring.

```
<defun frameEnvironment>≡
  (defun |frameEnvironment| (fname)
    "Get Named Frame Environment (aka Interactive)"
    (let ((frame (|findFrameInRing| fname)))
      (if frame
        (frameInteractive frame)
        (list (list nil))))))
```

### 20.5.4 Create a new, empty Interpreter Frame

```
<defun emptyInterpreterFrame>≡
  (defun |emptyInterpreterFrame| (name)
    "Create a new, empty Interpreter Frame"
    (declare (special |$HiFiAccess| |$HistList| |$HistListLen| |$HistListAct|
      |$HistRecord| |$localExposureDataDefault|))
    (list name ; frame name
      (list (list nil)) ; environment
      1 ; $IOindex
      |$HiFiAccess|
      |$HistList|
      |$HistListLen|
      |$HistListAct|
      |$HistRecord|
      nil ; $internalHistoryTable
      (copy-seq |$localExposureDataDefault|))) ; $localExposureData
```

### 20.5.5 Collecting up the Environment into a Frame

We can collect up all the current environment information into one frame element with this call. It creates a list of the current values of the global variables and returns this as a frame element.

```
(defun createCurrentInterpreterFrame)≡
  (defun |createCurrentInterpreterFrame| ()
    "Collecting up the Environment into a Frame"
    (declare (special |$interpreterFrameName| |$InteractiveFrame| |$IOindex|
      |$HiFiAccess| |$HistList| |$HistListLen| |$HistListAct| |$HistRecord|
      |$internalHistoryTable| |$localExposureData|))
    (list
      |$interpreterFrameName|
      |$InteractiveFrame|
      |$IOindex|
      |$HiFiAccess|
      |$HistList|
      |$HistListLen|
      |$HistListAct|
      |$HistRecord|
      |$internalHistoryTable|
      |$localExposureData|))
```

### 20.5.6 Update from the Current Frame

The frames are kept on a circular list. The first element on that list is known as “the current frame”. This will initialize all of the interesting interpreter data structures from that frame.

```
(defun updateFromCurrentInterpreterFrame)≡
  (defun |updateFromCurrentInterpreterFrame| ()
    "Update from the Current Frame"
    (let (tmp1)
      (declare (special |$interpreterFrameRing| |$interpreterFrameName|
        |$InteractiveFrame| |$IOindex| |$HiFiAccess| |$HistList| |$HistListLen|
        |$HistListAct| |$HistRecord| |$internalHistoryTable| |$localExposureData|
        |$frameMessages|))
        (setq tmp1 (first |$interpreterFrameRing|))
        (setq |$interpreterFrameName| (nth 0 tmp1))
        (setq |$InteractiveFrame|      (nth 1 tmp1))
        (setq |$IOindex|                (nth 2 tmp1))
        (setq |$HiFiAccess|             (nth 3 tmp1))
        (setq |$HistList|               (nth 4 tmp1))
        (setq |$HistListLen|            (nth 5 tmp1))
        (setq |$HistListAct|            (nth 6 tmp1))
        (setq |$HistRecord|             (nth 7 tmp1))
        (setq |$internalHistoryTable|   (nth 8 tmp1))
        (setq |$localExposureData|     (nth 9 tmp1))
        (when |$frameMessages|
          (|sayMessage|
            '("    Current interpreter frame is called"
              ,#(|bright| |$interpreterFrameName|))))))
```

### 20.5.7 Find a Frame in the Frame Ring by Name

Each frame contains its name as the 0th element. We simply walk all the frames and if we find one we return it.

```
(defun findFrameInRing)≡
  (defun |findFrameInRing| (name)
    "Find a Frame in the Frame Ring by Name"
    (let (result)
      (declare (special |$interpreterFrameRing|))
      (dolist (frame |$interpreterFrameRing|)
        (when (boot-equal (frameName frame) name)
          (setq result frame)))
      result))
```

### 20.5.8 Update the Current Interpreter Frame

This function collects the normal contents of the world into a frame object, places it first on the frame list, and then sets the current values of the world from the frame object.

```
<defun updateCurrentInterpreterFrame>≡
  (defun |updateCurrentInterpreterFrame| ()
    "Update the Current Interpreter Frame"
    (declare (special |$interpreterFrameRing|))
    (rplaca |$interpreterFrameRing| (|createCurrentInterpreterFrame|))
    (|updateFromCurrentInterpreterFrame|))
```

### 20.5.9 Move to the next Interpreter Frame in Ring

This function updates the current frame to make sure all of the current information is recorded. If there are more frame elements in the list then this will destructively move the current frame to the end of the list, that is, assume the frame list reads (1 2 3) this function will destructively change it to (2 3 1). Note: the `nconc2` function destructively inserts the second list at the end of the first.

```
<defun nextInterpreterFrame>≡
  (defun |nextInterpreterFrame| ()
    "Move to the next Interpreter Frame in Ring"
    (declare (special |$interpreterFrameRing|))
    (when (cdr |$interpreterFrameRing|)
      (setq |$interpreterFrameRing|
        (nconc2 (cdr |$interpreterFrameRing|)
          (list (car |$interpreterFrameRing|)))))
    (|updateFromCurrentInterpreterFrame|))
```

**20.5.10 Change to the Named Interpreter Frame**

```

<defun changeToNamedInterpreterFrame>≡
  (defun |changeToNamedInterpreterFrame| (name)
    "Change to the Named Interpreter Frame"
    (let (frame)
      (declare (special |$interpreterFrameRing|))
      (|updateCurrentInterpreterFrame|)
      (setq frame (|findFrameInRing| name))
      (when frame
        (setq |$interpreterFrameRing|
          (cons frame (nremove |$interpreterFrameRing| frame)))
        (|updateFromCurrentInterpreterFrame|))))

```

**20.5.11 Move to the previous Interpreter Frame in Ring**

```

<defun previousInterpreterFrame>≡
  (defun |previousInterpreterFrame| ()
    "Move to the previous Interpreter Frame in Ring"
    (let (tmp1 l b)
      (declare (special |$interpreterFrameRing|))
      (|updateCurrentInterpreterFrame|)
      (when (cdr |$interpreterFrameRing|)
        (setq tmp1 (reverse |$interpreterFrameRing|))
        (setq l (car tmp1))
        (setq b (nreverse (cdr tmp1)))
        (setq |$interpreterFrameRing| (nconc2 (cons l nil) b))
        (|updateFromCurrentInterpreterFrame|))))

```

**20.5.12 Add a New Interpreter Frame**

```

<defun addNewInterpreterFrame>≡
  (defun |addNewInterpreterFrame| (name)
    "Add a New Interpreter Frame"
    (declare (special |$interpreterFrameRing|))
    (if (null name)
        (|throwKeyedMsg| 's2iz0018 nil) ; you must provide a name for new frame
        (progn
          (|updateCurrentInterpreterFrame|)
          (dolist (f |$interpreterFrameRing|)
            (when (boot-equal name (frameName f)) ; existing frame with same name
              (|throwKeyedMsg| 's2iz0019 (list name))))
          (|initHistList|)
          (setq |$interpreterFrameRing|
                (cons (|emptyInterpreterFrame| name) |$interpreterFrameRing|))
          (|updateFromCurrentInterpreterFrame|)

```

## 20.6 Frame File Messages

*(Frame File Messages)*≡

S2IZ0016

The %1b system command takes arguments but no options.

S2IZ0017

%1b is not a valid frame name

S2IZ0018

You must provide a name for the new frame.

S2IZ0019

You cannot use the name %1b for a new frame because an existing frame already has that name.

S2IZ0020

There is only one frame active and therefore that cannot be closed. Furthermore, the frame name you gave is not the name of the current frame. The current frame is called %1b .

S2IZ0021

The current frame is the only active one. Issue %b )clear all %d to clear its contents.

S2IZ0022

There is no frame called %1b and so your command cannot be processed.

S2IZ0024

The names of the existing frames are: %1 %1

The current frame is the first one listed.

S2IZ0073

%b )frame import %d must be followed by the frame name. The names of objects in that frame can then optionally follow the frame name. For example,

%ceon %b )frame import calculus %d %ceoff

imports all objects in the %b calculus %d frame, and

%ceon %b )frame import calculus epsilon delta %d %ceoff

imports the objects named %b epsilon %d and %b delta %d from the frame %b calculus %d .

Please note that if the current frame contained any information about objects with these names, then that information would be cleared before the import took place.

S2IZ0074

You cannot import anything from the frame %1b because that is not the name of an existing frame.

S2IZ0075

You cannot import from the current frame (nor is there a need!).

S2IZ0076

User verification required:

do you really want to import everything from the frame %1b ?

If so, please enter %b y %d or %b yes %d :

S2IZ0077

On your request, AXIOM will not import everything from frame %1b.

S2IZ0078

Import from frame %1b is complete. Please issue %b )display all %d if you wish to see the contents of the current frame.

S2IZ0079

AXIOM cannot import %1b from frame %2b because it cannot be found.

## Chapter 21

# )help Command

### 21.1 help man page

*<help.help>*≡

=====

A.12. )help

=====

User Level Required: interpreter

Command Syntax:

- )help
- )help commandName
- )help syntax

Command Description:

This command displays help information about system commands. If you issue

)help

then this very text will be shown. You can also give the name or abbreviation of a system command to display information about it. For example,

)help clear

will display the description of the )clear system command.

The command

)help syntax

will give further information about the Axiom language syntax.

All this material is available in the AXIOM User Guide and in HyperDoc. In HyperDoc, choose the Commands item from the Reference menu.

```
=====
A.1.  Introduction
=====
```

System commands are used to perform AXIOM environment management. Among the commands are those that display what has been defined or computed, set up multiple logical AXIOM environments (frames), clear definitions, read files of expressions and commands, show what functions are available, and terminate AXIOM.

Some commands are restricted: the commands

```
)set userlevel interpreter
)set userlevel compiler
)set userlevel development
```

set the user-access level to the three possible choices. All commands are available at development level and the fewest are available at interpreter level. The default user-level is interpreter. In addition to the )set command (discussed in description of command )set ) you can use the HyperDoc settings facility to change the user-level. Click on [Settings] here to immediately go to the settings facility.

Each command listing begins with one or more syntax pattern descriptions plus examples of related commands. The syntax descriptions are intended to be easy to read and do not necessarily represent the most compact way of specifying all possible arguments and options; the descriptions may occasionally be redundant.

All system commands begin with a right parenthesis which should be in the first available column of the input line (that is, immediately after the input prompt, if any). System commands may be issued directly to AXIOM or be included in .input files.

A system command argument is a word that directly follows the command name and is not followed or preceded by a right parenthesis. A system command option follows the system command and is directly preceded by a right

parenthesis. Options may have arguments: they directly follow the option. This example may make it easier to remember what is an option and what is an argument:

```
)syscmd arg1 arg2 )opt1 opt1arg1 opt1arg2 )opt2 opt2arg1 ...
```

In the system command descriptions, optional arguments and options are enclosed in brackets (‘[’ and ‘]’). If an argument or option name is in *italics*, it is meant to be a variable and must have some actual value substituted for it when the system command call is made. For example, the syntax pattern description

```
)read fileName [)quietly]
```

would imply that you must provide an actual file name for `fileName` but need not use the `)quietly` option. Thus

```
)read matrix.input
```

is a valid instance of the above pattern.

System command names and options may be abbreviated and may be in upper or lower case. The case of actual arguments may be significant, depending on the particular situation (such as in file names). System command names and options may be abbreviated to the minimum number of starting letters so that the name or option is unique. Thus

```
)s Integer
```

is not a valid abbreviation for the `)set` command, because both `)set` and `)show` begin with the letter ‘s’. Typically, two or three letters are sufficient for disambiguating names. In our descriptions of the commands, we have used no abbreviations for either command names or options.

In some syntax descriptions we use a vertical line ‘|’ to indicate that you must specify one of the listed choices. For example, in

```
)set output fortran on | off
```

only `on` and `off` are acceptable words for following `boot`. We also sometimes use ‘...’ to indicate that additional arguments or options of the listed form are allowed. Finally, in the syntax descriptions we may also list the syntax of related commands.

                (say line))))))
    t))

```

## Chapter 22

# )history Command

### 22.1 history man page

*<history.help>*≡

=====

A.13. )history

=====

User Level Required: interpreter

Command Syntax:

- )history )on
- )history )off
- )history )write historyInputFileName
- )history )show [n] [both]
- )history )save savedHistoryName
- )history )restore [savedHistoryName]
- )history )reset
- )history )change n
- )history )memory
- )history )file
- %
- %% (n)
- )set history on | off

Command Description:

The history facility within AXIOM allows you to restore your environment to that of another session and recall previous computational results. Additional

commands allow you to review previous input lines and to create an .input file of the lines typed to AXIOM.

AXIOM saves your input and output if the history facility is turned on (which is the default). This information is saved if either of

```
)set history on
)history )on
```

has been issued. Issuing either

```
)set history off
)history )off
```

will discontinue the recording of information.

Whether the facility is disabled or not, the value of % in AXIOM always refers to the result of the last computation. If you have not yet entered anything, % evaluates to an object of type Variable('%). The function %% may be used to refer to other previous results if the history facility is enabled. In that case, %(n) is the output from step n if n > 0. If n < 0, the step is computed relative to the current step. Thus %(-1) is also the previous step, %(-2), is the step before that, and so on. If an invalid step number is given, AXIOM will signal an error.

The environment information can either be saved in a file or entirely in memory (the default). Each frame ( description of command )frame ) has its own history database. When it is kept in a file, some of it may also be kept in memory for efficiency. When the information is saved in a file, the name of the file is of the form FRAME.axh where 'FRAME' is the name of the current frame. The history file is placed in the current working directory (see description of command )cd ). Note that these history database files are not text files (in fact, they are directories themselves), and so are not in human-readable format.

The options to the )history command are as follows:

```
)change n
    will set the number of steps that are saved in memory to n. This option
    only has effect when the history data is maintained in a file. If you
    have issued )history )memory (or not changed the default) there is no
    need to use )history )change.
```

```
)on
    will start the recording of information. If the workspace is not empty,
    you will be asked to confirm this request. If you do so, the workspace
```

will be cleared and history data will begin being saved. You can also turn the facility on by issuing `)set history on`.

`)off`

will stop the recording of information. The `)history` `)show` command will not work after issuing this command. Note that this command may be issued to save time, as there is some performance penalty paid for saving the environment data. You can also turn the facility off by issuing `)set history off`.

`)file`

indicates that history data should be saved in an external file on disk.

`)memory`

indicates that all history data should be kept in memory rather than saved in a file. Note that if you are computing with very large objects it may not be practical to keep this data in memory.

`)reset`

will flush the internal list of the most recent workspace calculations so that the data structures may be garbage collected by the underlying Lisp system. Like `)history` `)change`, this option only has real effect when history data is being saved in a file.

`)restore [savedHistoryName]`

completely clears the environment and restores it to a saved session, if possible. The `)save` option below allows you to save a session to a file with a given name. If you had issued `)history` `)save jacobi` the command `)history` `)restore jacobi` would clear the current workspace and load the contents of the named saved session. If no saved session name is specified, the system looks for a file called `last.axh`.

`)save savedHistoryName`

is used to save a snapshot of the environment in a file. This file is placed in the current working directory (see description of command `)cd`). Use `)history` `)restore` to restore the environment to the state preserved in the file. This option also creates an input file containing all the lines of input since you created the workspace frame (for example, by starting your AXIOM session) or last did a `)clear all` or `)clear completely`.

`)show [n] [both]`

can show previous input lines and output results. `)show` will display up to twenty of the last input lines (fewer if you haven't typed in twenty lines). `)show n` will display up to `n` of the last input lines. `)show both` will display up to five of the last input lines and output results. `)show`

`n` both will display up to `n` of the last input lines and output results.

```
)write historyInputFile
  creates an .input file with the input lines typed since the start of the
  session/frame or the last )clear all or )clear completely. If
  historyInputFileName does not contain a period (‘.’) in the filename,
  .input is appended to it. For example, )history )write chaos and )history
  )write chaos.input both write the input lines to a file called
  chaos.input in your current working directory. If you issued one or more
  )undo commands, )history )write eliminates all input lines backtracked
  over as a result of )undo. You can edit this file and then use )read to
  have AXIOM process the contents.
```

Also See:

- o )frame
- o )read
- o )set
- o )undo

1

History recording is done in two different ways:

- all changes in variable bindings (i.e. previous values) are written to `$HistList`, which is a circular list
- all new bindings (including the binding to `%`) are written to a file called `histFileName()` one older session is accessible via the file `$oldHistFileName()`

## 22.2 Initialized history variables

The following global variables are used:

`$HistList`, `$HistListLen` and `$HistListAct` which is the actual number of “undoable” steps)

`$HistRecord` collects the input line, all variable bindings and the output of a step, before it is written to the file `histFileName()`.

`$HiFiAccess` is a flag, which is reset by `)history )off`

The result of step `n` can be accessed by `%n`, which is translated into a call of `fetchOutput(n)`. The `updateHist` is called after every interpreter step. The `putHist` function records all changes in the environment to `$HistList` and `$HistRecord`.

### 22.4.9 defun setHistoryCore

We case on the inCore argument value

If history is already on and is kept in the same location as requested (file or memory) then complain.

If history is not in use then start using the file or memory as requested. This is done by simply setting the `$useInternalHistoryTable` to the requested value, where T means use memory and NIL means use a file. We tell the user.

If history should be in memory, that is inCore is not NIL, and the history file already contains information we read the information from the file, store it in memory, and erase the history file. We modify `$useInternalHistoryTable` to T to indicate that we're maintaining the history in memory and tell the user.

Otherwise history must be on and in memory. We erase any old history file and then write the in-memory history to a new file

```

## 22.6 History File Messages

*(History File Messages)*≡

S2IH0001

You have not reached step %1b yet, and so its value cannot be supplied.

S2IH0002

Cannot supply value for step %1b because 1 is the first step.

S2IH0003

Step %1b has no value.

S2IH0004

The history facility is not on, so you cannot use %b %% %d .

S2IH0006

You have not used the correct syntax for the %b history %d command.

Issue %b )help history %d for more information.

S2IH0007

The history facility is already on.

S2IH0008

The history facility is now on.

S2IH0009

Turning on the history facility will clear the contents of the workspace.

Please enter %b y %d or %b yes %d if you really want to do this:

S2IH0010

The history facility is still off.

S2IH0011

The history facility is already off.

S2IH0012

The history facility is now off.

S2IH0013

The history facility is not on, so the .input file containing your user input cannot be created.

S2IH0014

Edit %b %1 %d to see the saved input lines.

S2IH0015

The argument %b n %d for %b )history )change n must be a nonnegative integer and your argument, %1b , is not one.

S2IH0016

The history facility is not on, so no information can be saved.

S2IH0018

The saved history file is %1b .

S2IH0019

There is no history file, so value of step %1b is undefined.

S2IH0022

No history information had been saved yet.

S2IH0023

%1b is not a valid filename for the history file.

S2IH0024

History information cannot be restored from %1b because the file does not exist.

S2IH0025

The workspace has been successfully restored from the history file %1b .

S2IH0026

The history facility command %1b cannot be performed because the history facility is not on.

S2IH0027

A value containing a %1b is being saved in a history file or a compiled input file INLIB. This type is not yet usable in other history operations. You might want to issue %b )history )off %d

S2IH0029

History information is already being maintained in an external file (and not in memory).

S2IH0030

History information is already being maintained in memory (and not in an external file).

S2IH0031

When the history facility is active, history information will be maintained in a file (and not in an internal table).

S2IH0032

When the history facility is active, history information will be maintained in memory (and not in an external file).

S2IH0034

Missing element in internal history table.

S2IH0035

Can't save the value of step number %1b. You can re-generate this value by running the input file %2b.

S2IH0036

The value specified cannot be saved to a file.

S2IH0037

You must specify a file name to the history save command

S2IH0038

You must specify a file name to the history write command

## Chapter 23

# )include Command

### 23.1 include man page

*<include.help>*≡

User Level Required: interpreter

Command Syntax:

```
)include filename
```

Command Description:

The `)include` command can be used in `.input` files to place the contents of another file inline with the current file. The path can be an absolute or relative pathname.

### 23.2 Functions

#### 23.2.1 defun nclloopInclude1

```
<defun nclloopInclude1>≡  
(defun |nclloopInclude1| (name n)  
  (let (a)  
    (if (setq a (|nclloopIncFileName| name))  
        (|nclloopInclude| a n)  
        n)))
```

### 23.2.2 Returns the first non-blank substring of the given string

```

<defun ncloopIncFileName>≡
  (defun |ncloopIncFileName| (string)
    "Returns the first non-blank substring of the given string"
    (let (fn)
      (unless (setq fn (|incFileName| string))
        (write-line (concat string " not found"))))
      fn))

```

### 23.2.3 Open the include file and read it in

The ncloopInclude0 function is part of the parser and lives in int-top.boot.

```

<defun ncloopInclude>≡
  (defun |ncloopInclude| (name n)
    "Open the include file and read it in"
    (with-open-file (st name) (|ncloopInclude0| st name n)))

```

### 23.2.4 Return the include filename

Given a string we return the first token from the string which is the first non-blank substring.

```

<defun incFileName>≡
  (defun |incFileName| (x)
    "Return the include filename"
    (car (|incBiteOff| x)))

```

**23.2.5 Return the next token**

Takes a sequence and returns the a list of the first token and the remaining string characters. If there are no remaining string characters the second string is of length 0. Effectively it "bites off" the first token in the string. If the string only 0 or more blanks it returns nil.

```
(defun incBiteOff)≡
  (defun |incBiteOff| (x)
    "Return the next token"
    (let (blank nonblank)
      (setq x (string x))
      (when (setq nonblank (position #\space x :test-not #'char=))
        (setq blank (position #\space x :start nonblank))
        (if blank
          (list (subseq x nonblank blank) (subseq x blank))
          (list (subseq x nonblank) ""))))))
```

## Chapter 24

# )library Command

### 24.1 library man page

*<library.help>*≡

```
=====
A.14.  )library
=====
```

User Level Required: interpreter

Command Syntax:

- )library libName1 [libName2 ...]
- )library )dir dirName
- )library )only objName1 [objlib2 ...]
- )library )noexpose

Command Description:

This command replaces the )load system command that was available in AXIOM releases before version 2.0. The )library command makes available to AXIOM the compiled objects in the libraries listed.

For example, if you )compile dopler.as in your home directory, issue )library dopler to have AXIOM look at the library, determine the category and domain constructors present, update the internal database with various properties of the constructors, and arrange for the constructors to be automatically loaded when needed. If the )noexpose option has not been given, the constructors will be exposed (that is, available) in the current frame.

If you compiled a file with the old system compiler, you will have an NRLIB present, for example, DOPLER.NRLIB, where DOPLER is a constructor abbreviation. The command )library DOPLER will then do the analysis and database updates as above.

To tell the system about all libraries in a directory, use )library )dir dirName where dirName is an explicit directory. You may specify ‘.’ as the directory, which means the current directory from which you started the system or the one you set via the )cd command. The directory name is required.

You may only want to tell the system about particular constructors within a library. In this case, use the )only option. The command )library dopler )only Test1 will only cause the Test1 constructor to be analyzed, autoloading, etc..

Finally, each constructor in a library are usually automatically exposed when the )library command is used. Use the )noexpose option if you not want them exposed. At a later time you can use )set expose add constructor to expose any hidden constructors.

Note for AXIOM beta testers: At various times this command was called )local and )with before the name )library became the official name.

## Chapter 25

# )lisp Command

### 25.1 lisp man page

*(lisp.help)*≡

```
=====
A.15.  )lisp
=====
```

User Level Required: development

Command Syntax:

- )lisp [lispExpression]

Command Description:

This command is used by AXIOM system developers to have single expressions evaluated by the Lisp system on which AXIOM is built. The `lispExpression` is read by the Lisp reader and evaluated. If this expression is not complete (unbalanced parentheses, say), the reader will wait until a complete expression is entered.

Since this command is only useful for evaluating single expressions, the `)fin` command may be used to drop out of AXIOM into Lisp.

Also See:

- o `)system`
- o `)boot`
- o `)fin`

## 25.2 Functions

This command is in the list of `$noParseCommands` 7.1.3 which means that its arguments are passed verbatim. This will eventually result in a call to the function `handleNoParseCommands` 7.2.1

---

<sup>1</sup> “system” (37 p 385) “boot” (9 p 91) “fin” (19 p 149)

## Chapter 26

# )load Command

### 26.1 load man page

*<load.help>*≡

=====

A.16. )load

=====

User Level Required: interpreter

Command Description:

This command is obsolete. Use )library instead.

## Chapter 27

# )ltrace Command

### 27.1 ltrace man page

`<ltrace.help>`≡

=====

A.17. )ltrace

=====

User Level Required: development

Command Syntax:

This command has the same arguments as options as the )trace command.

Command Description:

This command is used by AXIOM system developers to trace Lisp or BOOT functions. It is not supported for general use.

Also See:

- o )boot
- o )lisp
- o )trace

## 27.2 Variables Used

## 27.3 Functions

## Chapter 28

# )pquit Command

### 28.1 pquit man page

*<pquit.help>*≡

=====

A.18. )pquit

=====

User Level Required: interpreter

Command Syntax:

- )pquit

Command Description:

This command is used to terminate AXIOM and return to the operating system. Other than by redoing all your computations or by using the )history )restore command to try to restore your working environment, you cannot return to AXIOM in the same state.

)pquit differs from the )quit in that it always asks for confirmation that you want to terminate AXIOM (the ‘‘p’’ is for ‘‘protected’’). When you enter the )pquit command, AXIOM responds

Please enter y or yes if you really want to leave the interactive  
environment and return to the operating system:

If you respond with y or yes, you will see the message

You are now leaving the AXIOM interactive environment.  
 Issue the command `axiom` to the operating system to start a new session.

and AXIOM will terminate and return you to the operating system (or the environment from which you invoked the system). If you responded with something other than `y` or `yes`, then the message

You have chosen to remain in the AXIOM interactive environment.

will be displayed and, indeed, AXIOM would still be running.

Also See:

- o `)fin`
- o `)history`
- o `)close`
- o `)quit`
- o `)system`

1

## 28.2 Functions

### 28.2.1 The top level `pquit` command

```
<defun pquit>≡
  (defun |pquit| ()
    "The top level pquit command"
    (|pquitSpad2Cmd|))
```

### 28.2.2 The top level `pquit` command handler

```
<defun pquitSpad2Cmd>≡
  (defun |pquitSpad2Cmd| ()
    "The top level pquit command handler"
    (let ((|$quitCommandType| ' |protected|))
      (declare (special |$quitCommandType|))
      (|quitSpad2Cmd|)))
```

---

<sup>1</sup> “`fin`” (19 p 149) “`history`” (22.4.7 p 183) “`close`” (13.2.2 p 113) “`quit`” (29.2.1 p 234) “`system`” (37 p 385)

This command is in the list of `$noParseCommands` 7.1.3 which means that its arguments are passed verbatim. This will eventually result in a call to the function `handleNoParseCommands` 7.2.1

## Chapter 29

# )quit Command

### 29.1 quit man page

`<quit.help>≡`

=====

A.19. )quit

=====

User Level Required: interpreter

Command Syntax:

- )quit
- )set quit protected | unprotected

Command Description:

This command is used to terminate AXIOM and return to the operating system. Other than by redoing all your computations or by using the )history )restore command to try to restore your working environment, you cannot return to AXIOM in the same state.

)quit differs from the )pquit in that it asks for confirmation only if the command

)set quit protected

has been issued. Otherwise, )quit will make AXIOM terminate and return you to the operating system (or the environment from which you invoked the system).

The default setting is `)set quit protected` so that `)quit` and `)pquit` behave in the same way. If you do issue

```
)set quit unprotected
```

we suggest that you do not (somehow) assign `)quit` to be executed when you press, say, a function key.

Also See:

- o `)fin`
- o `)history`
- o `)close`
- o `)pquit`
- o `)system`

1

## 29.2 Functions

### 29.2.1 The top level quit command

```
<defun quit>≡
(defun |quit| ()
  "The top level quit command"
  (|quitSpad2Cmd|))
```

### 29.2.2 The top level quit command handler

```
<defun quitSpad2Cmd>≡
(defun |quitSpad2Cmd| ()
  "The top level quit command handler"
  (declare (special |$quitCommandType|))
  (if (eq |$quitCommandType| '|protected|)
      (let (x)
        (setq x (upcase (|queryUserKeyedMsg| 's2iz0031 nil)))
        (when (memq (string2id-n x 1) '(y yes)) (|leaveScratchpad|))
        (|sayKeyedMsg| 's2iz0032 nil)
        (tersyscommand))
      (|leaveScratchpad|)))
```

---

<sup>1</sup> “fin” (19 p 149) “history” (22.4.7 p 183) “close” (13.2.2 p 113) “pquit” (28.2.1 p 230) “system” (37 p 385)

### 29.2.3 Leave the Axiom interpreter

```
<defun leaveScratchpad>≡  
(defun |leaveScratchpad| ()  
  "Leave the Axiom interpreter"  
  (bye))
```

This command is in the list of `$noParseCommands` 7.1.3 which means that its arguments are passed verbatim. This will eventually result in a call to the function `handleNoParseCommands` 7.2.1

## Chapter 30

# )read Command

### 30.1 read man page

`<read.help>`≡

```
=====
A.20.  )read
=====
```

User Level Required: interpreter

Command Syntax:

- )read [fileName]
- )read [fileName] [ ]quiet [ ]ifthere]

Command Description:

This command is used to read .input files into AXIOM. The command

```
)read matrix.input
```

will read the contents of the file matrix.input into AXIOM. The ‘.input’ file extension is optional. See the AXIOM User Guide index for more information about .input files.

This command remembers the previous file you edited, read or compiled. If you do not specify a file name, the previous file will be read.

The )ifthere option checks to see whether the .input file exists. If it does not, the )read command does nothing. If you do not use this option and the

file does not exist, you are asked to give the name of an existing `.input` file.

The `)quiet` option suppresses output while the file is being read.

Also See:

- o `)compile`
- o `)edit`
- o `)history`

---

<sup>1</sup> “compile” (?? p ??) “edit” (18.2.1 p 146) “history” (22.4.7 p 183)

## Chapter 31

# )savesystem Command

### 31.1 savesystem man page

*<savesystem.help>*≡

=====

A.8. )savesystem

=====

User Level Required: interpreter

Command Syntax:

- )savesystem filename

Command Description:

This command is used to save an AXIOM image to disk. This creates an executable file which, when started, has everything loaded into it that was there when the image was saved. Thus, after executing commands which cause the loading of some packages, the command:

)savesystem /tmp/savesys

will create an image that can be restarted with the UNIX command:

axiom -ws /tmp/savesys

This new system will not need to reload the packages and domains that were already loaded when the system was saved.

There is currently a restriction that only systems started with the command "AXIOMsys" may be saved.

## Chapter 32

# )set Command

### 32.1 set man page

`<set.help>`≡

=====

A.21. )set

=====

User Level Required: interpreter

Command Syntax:

- )set
- )set label1 [... labelN]
- )set label1 [... labelN] newValue

Command Description:

The )set command is used to view or set system variables that control what messages are displayed, the type of output desired, the status of the history facility, the way AXIOM user functions are cached, and so on. Since this collection is very large, we will not discuss them here. Rather, we will show how the facility is used. We urge you to explore the )set options to familiarize yourself with how you can modify your AXIOM working environment. There is a HyperDoc version of this same facility available from the main HyperDoc menu. Click [\[here\]](#) to go to it.

The )set command is command-driven with a menu display. It is tree-structured. To see all top-level nodes, issue )set by itself.

```
)set
```

Variables with values have them displayed near the right margin. Subtrees of selections have ‘‘...’’ displayed in the value field. For example, there are many kinds of messages, so issue `)set message` to see the choices.

```
)set message
```

The current setting for the variable that displays whether computation times are displayed is visible in the menu displayed by the last command. To see more information, issue

```
)set message time
```

This shows that time printing is on now. To turn it off, issue

```
)set message time off
```

As noted above, not all settings have so many qualifiers. For example, to change the `)quit` command to being unprotected (that is, you will not be prompted for verification), you need only issue

```
)set quit unprotected
```

Also See:

- o `)quit`

1

## 32.2 Overview

This section contains tree of information used to initialize the `)set` command in the interpreter. The current list is:

Variable	Description	Current Value
compiler	Library compiler options	...
breakmode	execute break processing on error	break
expose	control interpreter constructor exposure	...
functions	some interpreter function options	...
fortran	view and set options for FORTRAN output	...
kernel	library functions built into the kernel for efficiency	...
hyperdoc	options in using HyperDoc	...
help	view and set some help options	...
history	save workspace values in a history file	on
messages	show messages for various system features	...
naglink	options for NAGLink	...
output	view and set some output options	...
quit	protected or unprotected quit	unprotected
streams	set some options for working with streams	...
system	set some system development variables	...
userlevel	operation access level of system user	development

Variables with current values of ... have further sub-options. For example, issue `)set system` to see what the options are for system. For more information, issue `)help set .`

## 32.3 Variables Used

## 32.4 Functions

### 32.4.1 Initialize the set variables

The argument `settree` is initially the `$setOption` variable. The fourth element is a union-style switch symbol. The fifth element is usually a variable to set. The sixth element is a subtree to recurse for the `TREE` switch. The seventh

---

<sup>1</sup>“quit” (29.2.1 p 234)

element is usually the default value. For more detailed explanations see the list structure section 32.5.

```

<defun initializeSetVariables>≡
  (defun |initializeSetVariables| (settree)
    "Initialize the set variables"
    (dolist (setdata settree)
      (case (fourth setdata)
        (FUNCTION
          (if (functionp (fifth setdata))
              (funcall (fifth setdata) '|%initialize%|)
              (|sayMSG| (concatenate 'string "    Function not implemented. "
                                     (package-name *package*) ":" (string (fifth setdata))))))
        (INTEGER (set (fifth setdata) (seventh setdata)))
        (STRING  (set (fifth setdata) (seventh setdata)))
        (LITERALS
          (set (fifth setdata) (|translateYesNo2TrueFalse| (seventh setdata))))
        (TREE   (|initializeSetVariables| (sixth setdata))))))

```

### 32.4.2 Reset the workspace variables

```

<defun resetWorkspaceVariables>≡

  (|sayBrightly|
    '("Variables with current values of" ,@(|bright| "...")
      "have further sub-options. For example,")
  (|sayBrightly|
    '("issue" ,@(|bright| ")set " ,subname
      " to see what the options are for" ,@(|bright| subname) ".")
    |%l| "For more information, issue" ,@(|bright| ")help set") "."))))

```

### 32.4.5 Translate options values to t or nil

```

<defun translateYesNo2TrueFalse>≡
  (defun |translateYesNo2TrueFalse| (x)
    "Translate options values to t or nil"
    (cond
      ((|member| x '(|yes| |on|)) t)
      ((|member| x '(|no| |off|)) nil)
      (t x)))

```

### 32.4.6 Translate t or nil to option values

```

<defun translateTrueFalse2YesNo>≡
  (defun |translateTrueFalse2YesNo| (x)
    "Translate t or nil to option values"
    (cond
      ((eq x t) '|on|)
      ((null x) '|off|)
      (t x)))

```

## 32.5 The list structure

The structure of each list item consists of 7 items. Consider this example:

```
(userlevel
  "operation access level of system user"
  interpreter
  LITERALS
  $UserLevel
  (interpreter compiler development)
  development)
```

The list looks like (the names in bold are accessor names that can be found in **property.lisp.pamphlet[1]**. Look for "setName".):

**1** *Name* the keyword the user will see. In this example the user would say **)set output userlevel**".

**2** *Label* the message the user will see. In this example the user would see "operation access level of system user".

**3** *Level* the level where the command will be accepted. There are three levels: interpreter, compiler, development. These commands are restricted to keep the user from causing damage.

**4** *Type* a symbol, one of **FUNCTION**, **INTEGER**, **STRING**, **LITERALS**, **FILENAME** or **TREE**.

**5** *Var*

FUNCTION is the function to call

INTEGER is the variable holding the current user setting.

STRING is the variable holding the current user setting.

LITERALS variable which holds the current user setting.

FILENAME is the variable that holds the current user setting.

TREE

**6** *Leaf*

FUNCTION is the list of all possible values

INTEGER is the range of possible values

STRING is a list of all possible values

LITERALS is a list of all of the possible values

FILENAME is the function to check the filename

TREE

7 Def is the default value

FUNCTION is the default setting

INTEGER is the default setting

STRING is the default setting

LITERALS is the default setting

FILENAME is the default value

TREE

## 32.6 breakmode

----- The breakmode Option -----

Description: execute break processing on error

The breakmode option may be followed by any one of the following:

```
nobreak
-> break
query
resume
fastlinks
```

The current setting is indicated.

### 32.6.1 defvar \$BreakMode

$\langle initvars \rangle + \equiv$

```
(defvar |$BreakMode| ' |nobreak| "execute break processing on error")
```

$\langle breakmode \rangle \equiv$

```
(|breakmode|
 "execute break processing on error"
 |interpreter|
 LITERALS
 |$BreakMode|
 (|nobreak| |break| |query| |resume| |fastlinks|)
 |nobreak|) ; needed to avoid possible startup looping
```

## 32.7 debug

Current Values of debug Variables

Variable	Description	Current Value
lambdtype	Show type information for #1 syntax	off
dalymode	Interpret leading open paren as lisp	off

```

<debug>≡
  (|debug|
   "debug options"
   |interpreter|
   TREE
   |novar|
   (
    <debuglambdtype>
    <debugdalymode>
   ))

```

## 32.8 debug lambda type

----- The lambdtype Option -----

Description: Show type information for #1 syntax

### 32.8.1 defvar \$lambdtype

```

<initvars>+≡
  (defvar $lambdtype nil "show type information for #1 syntax")

```

```

<debuglambdtype>≡
  (|lambdtype|
   "show type information for #1 syntax"
   |interpreter|
   LITERALS
   $lambdtype
   (|on| |off|)
   |off|)

```

## 32.9 debug dalymode

The `$dalymode` variable is used in a case statement in `intloopReadConsole`. This variable can be set to any non-nil value. When not nil the interpreter will send any line that begins with an "(" to be sent to the underlying lisp. This is useful for debugging Axiom. The normal value of this variable is NIL.

This variable was created as an alternative to prefixing every lisp command with `)lisp`. When doing a lot of debugging this is tedious and error prone. This variable was created to shortcut that process. Clearly it breaks some semantics of the language accepted by the interpreter as parens are used for grouping expressions.

----- The dalymode Option -----

Description: Interpret leading open paren as lisp

### 32.9.1 defvar \$dalymode

```
<initvars>+≡
  (defvar $dalymode nil "Interpret leading open paren as lisp")
```

```
<debugdalymode>≡
  (|dalymode|
    "Interpret leading open paren as lisp"
    |interpreter|
    LITERALS
    $dalymode
    (|on| |off|)
    |off|)
```

## 32.10 compiler

Current Values of compiler Variables

Variable	Description	Current Value
output	library in which to place compiled code	
input	controls libraries from which to load compiled code	
args	arguments for compiling AXIOM code	
	-O -Fasy -Fao -Flsp -laxiom -Mno-AXL_W_WillObsolete	
	-DAxiom -Y \$AXIOM/algebra	

```

<compiler>≡
  (|compiler|
    "Library compiler options"
    |interpreter|
    TREE
    |novar|
    (
      <compileroutput>
      <compilerinput>
      <compilerargs>
    ))

```

## 32.11 compiler output

----- The output Option -----

Description: library in which to place compiled code

```

<compileroutput>≡
  (|output|
    "library in which to place compiled code"
    |interpreter|
    FUNCTION
    |setOutputLibrary|
    NIL
    |htSetOutputLibrary|
    )

```

## 32.12 Variables Used

## 32.13 Functions

### 32.13.1 The set output command handler

```

<defun setOutputLibrary>≡
  (defun |setOutputLibrary| (arg)
    "The set output command handler"
    (let (fn)
      (declare (special |$outputLibraryName|))
      (cond
        ((eq arg '|%initialize%|) (setq |$outputLibraryName| nil))
        ((eq arg '|%display%|) (or |$outputLibraryName| "user.lib"))
        ((or (null arg) (eq arg '|%describe%|) (eq (car arg) '?)) (/= (|#| arg) 1))
          (|describeOutputLibraryArgs|))
      (t
       (when (filep (setq fn (stringimage (car arg))))
         (setq fn (truename fn)))
       (|openOutputLibrary| (setq |$outputLibraryName| fn))))))

```

### 32.13.2 Describe the set output library arguments

```

<defun describeOutputLibraryArgs>≡
  (defun |describeOutputLibraryArgs| ()
    "Describe the set output library arguments"
    (|sayBrightly| (list
      '|%b| ")"set compiler output library"
      '|%d| "is used to tell the compiler where to place"
      '|%l| "compiled code generated by the library compiler. By default it goes"
      '|%l| "in a file called"
      '|%b| "user.lib"
      '|%d| "in the current directory.")))

```

### 32.13.3 Open the output library

The input-libraries and output-library are now truename based.

```
<defun openOutputLibrary>≡
  (defun |openOutputLibrary| (lib)
    "Open the output library"
    (declare (special output-library input-libraries))
    (|dropInputLibrary| lib)
    (setq output-library (truename lib))
    (push output-library input-libraries))
```

## 32.14 compiler input

----- The input Option -----

Description: controls libraries from which to load compiled code

)set compiler input add library is used to tell AXIOM to add library to the front of the path which determines where compiled code is loaded from.

)set compiler input drop library is used to tell AXIOM to remove library from this path.

```
<compilerinput>≡
  (|input|
    "controls libraries from which to load compiled code"
    |interpreter|
    FUNCTION
    |setInputLibrary|
    NIL
    |htSetInputLibrary|)
```

## 32.15 Variables Used

## 32.16 Functions

### 32.16.1 The set input library command handler

The input-libraries is now maintained as a list of truenames.

```
(defun setInputLibrary)≡
  (defun |setInputLibrary| (arg)
    "The set input library command handler"
    (declare (special input-libraries))
    (let (tmp1 filename act)
      (cond
        ((eq arg '|%initialize%|) t)
        ((eq arg '|%display%|) (mapcar #'namestring input-libraries))
        ((or (null arg) (eq arg '|%describe%|) (eq (car arg) '?))
         (|describeInputLibraryArgs|))
        ((and (pairp arg)
              (progn
               (setq act (qcar arg))
               (setq tmp1 (qcdr arg))
               (and (pairp tmp1)
                    (eq (qcdr tmp1) nil)
                    (progn (setq filename (qcar tmp1)) t))))
         (setq act (|selectOptionLC| act '(|add| |drop|) nil)))
      (cond
        ((eq act '|add|)
         (|addInputLibrary| (truenam (stringimage filename))))
        ((eq act '|drop|)
         (|dropInputLibrary| (truenam (stringimage filename)))))
      (t (|setInputLibrary| nil)))))
```

### 32.16.2 Describe the set input library arguments

```

<defun describeInputLibraryArgs>≡
  (defun |describeInputLibraryArgs| ()
    "Describe the set input library arguments"
    (|sayBrightly| (list
      '|%b| ")set compiler input add library"
      '|%d| "is used to tell AXIOM to add"
      '|%b| "library"
      '|%d| "to"
      '|%l| "the front of the path used to find compile code."
      '|%l|
      '|%b| ")set compiler input drop library"

      '|%l|
      '|%b| "\" |$asharpCmdlineFlags| "\"
      '|%d|)))

```

## 32.20 expose

----- The expose Option -----

Description: control interpreter constructor exposure

The following groups are explicitly exposed in the current frame (called initial ):

```

        basic
    categories
        naglink
        anna

```

The following constructors are explicitly exposed in the current frame:

```

        there are no explicitly exposed constructors

```

The following constructors are explicitly hidden in the current frame:

```

        there are no explicitly hidden constructors

```

When )set expose is followed by no arguments, the information you now see is displayed. When followed by the initialize argument, the exposure group data in the file interp.exposed is read and is then available. The arguments add and drop are used to add or drop exposure groups or explicit constructors from the local frame exposure data. Issue

```

        )set expose add    or    )set expose drop

```

for more information.

```

⟨expose⟩≡

      ⟨functionscache⟩
      ⟨functionscompile⟩
      ⟨functionsrecurrence⟩
    )
  )

```

## 32.24 functions cache

----- The cache Option -----

Description: number of function results to cache

)set functions cache is used to tell AXIOM how many values computed by interpreter functions should be saved. This can save quite a bit of time in recursive functions, though one must consider that the cached values will take up (perhaps valuable) room in the workspace.

The value given after cache must either be the word all or a positive integer. This may be followed by any number of function names whose cache sizes you wish to so set. If no functions are given, the default cache size is set.

Examples:    )set fun cache all  
              )set fun cache 10 f g Legendre

In general, functions will cache no returned values.

```
{functions cache}≡
(|cache|
  "number of function results to cache"
  |interpreter|
  FUNCTION
  |setFunctionsCache|
  NIL
  |htSetCache|)

```

### linker

----- The linker Option -----

Description: linker arguments (e.g. libraries to search)

)set fortran calling linkerargs is used to pass arguments to the linker when using mkFort to create functions which call Fortran code. For example, it might give a list of libraries to be searched, and their locations. The string is passed verbatim, so must be the correct syntax for the particular linker being used.

Example: )set fortran calling linker "-lxlif"

The current setting is -lxlif

### 32.28.31 defvar \$fortranLibraries

  )

```

### 32.29.1 kernelwarn

----- The warn Option -----

Description: warn when re-definition is attempted

Some AXIOM library functions are compiled into the kernel for efficiency reasons. To prevent them being re-defined when loaded from a library they are specially protected. If a user wishes to know when an attempt is made to re-define such a function, he or she should issue the command:

```
)set kernel warn on
```

To restore the default behaviour, he or she should issue the command:

```
)set kernel warn off
```

```

## 32.35 output

The result of the `)set output` command is:

Variable	Description	Current Value
abbreviate	abbreviate type names	off
algebra	display output in algebraic form	On:CONSOLE
characters	choose special output character set	plain
fortran	create output in FORTRAN format	Off:CONSOLE
fraction	how fractions are formatted	vertical
length	line length of output displays	77
mathml	create output in MathML style	Off:CONSOLE
openmath	create output in OpenMath style	Off:CONSOLE
script	display output in SCRIPT formula format	Off:CONSOLE
scripts	show subscripts,... linearly	off
showeditor	view output of <code>)show</code> in editor	off
tex	create output in TeX style	Off:CONSOLE

Since the output option has a bunch of sub-options each suboption is defined within the output structure.

```

LITERALS  
|\$abbreviateTypes|  
(|on| |off|)  
|off|)

### 32.35.3 algebra

----- The algebra Option -----

Description: display output in algebraic form

)set output algebra is used to tell AXIOM to turn algebra-style output printing on and off, and where to place the output. By default, the destination for the output is the screen but printing is turned off.

Syntax: )set output algebra <arg>

where arg can be one of

on	turn algebra printing on (default state)
off	turn algebra printing off
console	send algebra output to screen (default state)
fp<.fe>	send algebra output to file with file prefix fp and file extension .fe. If not given, .fe defaults to .spout.

If you wish to send the output to a file, you may need to issue this command twice: once with on and once with the file name. For example, to send algebra output to the file polymer.spout, issue the two commands

```
)set output algebra on
)set output algebra polymer
```

The output is placed in the directory from which you invoked AXIOM or the one you set with the )cd system command.

The current setting is: On:CONSOLE

### 32.35.4 defvar \$algebraFormat

### 32.35.10 fortran

----- The fortran Option -----

Description: create output in FORTRAN format

)set output fortran is used to tell AXIOM to turn FORTRAN-style output printing on and off, and where to place the output. By default, the destination for the output is the screen but printing is turned off.

Also See: )set fortran

Syntax: )set output fortran <arg>  
 where arg can be one of

on	turn FORTRAN printing on
off	turn FORTRAN printing off (default state)
console	send FORTRAN output to screen (default state)
fp<.fe>	send FORTRAN output to file with file prefix fp and file extension .fe. If not given, .fe defaults to .sfort.

If you wish to send the output to a file, you must issue this command twice: once with on and once with the file name. For example, to send FORTRAN output to the file polymer.sfort, issue the two commands

```

)set output fortran on
)set output fortran polymer

```

The output is placed in the directory from which you invoked AXIOM or the one you set with the )cd system command. The current setting is: Off:CONSOLE

**32.35.24 openmath**

----- The openmath Option -----

Description: create output in OpenMath style

)set output tex is used to tell AXIOM to turn OpenMath output printing on and off, and where to place the output. By default, the destination for the output is the screen but printing is turned off.

Syntax: )set output tex <arg>

where arg can be one of

on	turn OpenMath printing on
off	turn OpenMath printing off (default state)
console	send OpenMath output to screen (default state)
fp<.fe>	send OpenMath output to file with file prefix fp and file extension .fe. If not given, .fe defaults to .sopen.

If you wish to send the output to a file, you must issue this command twice: once with on and once with the file name. For example, to send OpenMath output to the file polymer.sopen, issue the two commands

```
)set output openmath on
)set output openmath polymer
```

The output is placed in the directory from which you invoked AXIOM or the one you set with the )cd system command. The current setting is: Off:CONSOLE

**32.35.29 script**

----- The script Option -----

Description: display output in SCRIPT formula format

)set output script is used to tell AXIOM to turn IBM Script formula-style output printing on and off, and where to place the output. By default, the destination for the output is the screen but printing is turned off.

Syntax: )set output script <arg>  
           where arg can be one of  
           on       turn IBM Script formula printing on  
           off       turn IBM Script formula printing off  
                   (default state)  
           console send IBM Script formula output to screen  
                   (default state)  
           fp<.fe> send IBM Script formula output to file with file  
                   prefix fp and file extension .fe. If not given,  
                   .fe defaults to .sform.

If you wish to send the output to a file, you must issue this command twice: once with on and once with the file name. For example, to send IBM Script formula output to the file polymer.sform, issue the two commands

```
)set output script on
)set output script polymer
```

The output is placed in the directory from which you invoked AXIOM or the one you set with the )cd system command. The current setting is: Off:CONSOLE

**32.35.38 tex**

----- The tex Option -----

Description: create output in TeX style

)set output tex is used to tell AXIOM to turn TeX-style output printing on and off, and where to place the output. By default, the destination for the output is the screen but printing is turned off.

Syntax: )set output tex <arg>

where arg can be one of

on	turn TeX printing on
off	turn TeX printing off (default state)
console	send TeX output to screen (default state)
fp<.fe>	send TeX output to file with file prefix fp and file extension .fe. If not given, .fe defaults to .stex.

If you wish to send the output to a file, you must issue this command twice: once with on and once with the file name. For example, to send TeX output to the file polymer.stex, issue the two commands

```
)set output tex on
)set output tex polymer
```

The output is placed in the directory from which you invoked AXIOM or the one you set with the )cd system command. The current setting is: Off:CONSOLE

<initvars>+≡
  (defvar |$setOptionNames| (mapcar #'car |$setOptions|))

```

```

<postvars>+≡
  (eval-when (eval load)
    (|initializeSetVariables| |$setOptions|))

```

## 32.40 Set code

### 32.40.1 defun set

```
<defun set>≡  
  (defun |set| (l)  
    (declare (special |$setOptions|))  
    (|set1| l |$setOptions|))
```

### 32.40.2 defun set1

This function will be called with the top level arguments to `)set`. For instance, given the command

```
)set break break
```

this function gets

```
(set1 (|break| |break|) ....)
```

and given the command

```
)set mes auto off
```

this function gets

```
(set1 (|mes| |auto| |off|) ....)
```

which, because “message” is a TREE, generates the recursive call:

```
(set1 (|auto| |off|) <the message subtree>)
```

The “autoload” subtree is a FUNCTION (`printLoadMessages`), which gets called with `%describe%`

```
<defun set1>≡
(defun |set1| (l settree)
  (let (|$setOptionNames| arg setdata st setfunarg num upperlimit arg2)
    (declare (special |$setOptionNames| |$UserLevel| |$displaySetValue|))

      nil))))))

```

## Chapter 33

# )show Command

### 33.1 show man page

*(show.help)*≡

=====

A.22.   )show

=====

User Level Required:   interpreter

Command Syntax:

- )show nameOrAbbrev
- )show nameOrAbbrev )operations
- )show nameOrAbbrev )attributes

Command Description:

This command displays information about AXIOM domain, package and category constructors. If no options are given, the )operations option is assumed. For example,

```
)show POLY
)show POLY )operations
)show Polynomial
)show Polynomial )operations
```

each display basic information about the Polynomial domain constructor and then provide a listing of operations. Since Polynomial requires a Ring (for example, Integer) as argument, the above commands all refer to a unspecified ring R. In the list of operations, \$ means Polynomial(R).

The basic information displayed includes the signature of the constructor (the name and arguments), the constructor abbreviation, the exposure status of the constructor, and the name of the library source file for the constructor.

If operation information about a specific domain is wanted, the full or abbreviated domain name may be used. For example,

```
)show POLY INT
)show POLY INT )operations
)show Polynomial Integer
)show Polynomial Integer )operations
```

are among the combinations that will display the operations exported by the domain `Polynomial(Integer)` (as opposed to the general domain constructor `Polynomial`). Attributes may be listed by using the `)attributes` option.

Also See:

- o `)display`
- o `)set`
- o `)what`

---

<sup>1</sup> “display” (17.2.1 p 137) “set” (32.40.1 p 372) “what” (40.1.2 p 467)

## Chapter 34

# )spool Command

### 34.1 spool man page

*<spool.help>*≡

=====

A.23. )spool

=====

User Level Required: interpreter

Command Syntax:

- )spool [fileName]
- )spool

Command Description:

This command is used to save (spool) all AXIOM input and output into a file, called a spool file. You can only have one spool file active at a time. To start spool, issue this command with a filename. For example,

)spool integrate.out

To stop spooling, issue )spool with no filename.

If the filename is qualified with a directory, then the output will be placed in that directory. If no directory information is given, the spool file will be placed in the current directory. The current directory is the directory from which you started AXIOM or is the directory you specified using the )cd command.

Also See:

- o )cd

1

---

<sup>1</sup>“cd” (11 p 99)

## Chapter 35

# )summary Command

### 35.1 summary man page

*<summary.help>*≡

```
)credits      : list the people who have contributed to Axiom

)help <command> gives more information
)quit        : exit AXIOM

)abbreviation : query, set and remove abbreviations for constructors
)cd           : set working directory
)clear        : remove declarations, definitions or values
)close        : throw away an interpreter client and workspace
)compile      : invoke constructor compiler
)display      : display Library operations and objects in your workspace
)edit         : edit a file
)frame        : manage interpreter workspaces
)history      : manage aspects of interactive session
)library      : introduce new constructors
)lisp         : evaluate a LISP expression
)read         : execute AXIOM commands from a file
)savesystem   : save LISP image to a file
)set          : view and set system variables
)show         : show constructor information
)spool        : log input and output to a file
)synonym      : define an abbreviation for system commands
)system       : issue shell commands
)trace        : trace execution of functions
)undo         : restore workspace to earlier state
)what         : search for various things by name
```

### 35.1.1 defun summary

```
<defun summary>≡  
  (defun |summary| (l)  
    (declare (ignore l))  
    (obey (strconc "cat " (getenv "AXIOM") "/doc/spadhelp/summary.help")))
```

## Chapter 36

# )synonym Command

### 36.1 synonym man page

*<synonym.help>*≡

=====

A.24. )synonym

=====

User Level Required: interpreter

Command Syntax:

- )synonym
- )synonym synonym fullCommand
- )what synonyms

Command Description:

This command is used to create short synonyms for system command expressions. For example, the following synonyms might simplify commands you often use.

)synonym save	history )save
)synonym restore	history )restore
)synonym mail	system mail
)synonym ls	system ls
)synonym fortran	set output fortran

Once defined, synonyms can be used in place of the longer command expressions. Thus

)fortran on

is the same as the longer

)set fortran output on

To list all defined synonyms, issue either of

)synonyms

)what synonyms

To list, say, all synonyms that contain the substring ‘‘ap’’, issue

)what synonyms ap

Also See:

- o )set

- o )what

1

This command is in the list of `$noParseCommands` 7.1.3 which means that its arguments are passed verbatim. This will eventually result in a call to the function `handleNoParseCommands` 7.2.1

---

<sup>1</sup> “set” (32.40.1 p 372) “what” (40.1.2 p 467)

## Chapter 37

# )system Command

### 37.1 system man page

*<system.help>*≡

=====

A.25. )system

=====

User Level Required: interpreter

Command Syntax:

- )system cmdExpression

Command Description:

This command may be used to issue commands to the operating system while remaining in AXIOM. The cmdExpression is passed to the operating system for execution.

To get an operating system shell, issue, for example, )system sh. When you enter the key combination, Ctrl-D (pressing and holding the Ctrl key and then pressing the D key) the shell will terminate and you will return to AXIOM. We do not recommend this way of creating a shell because Lisp may field some interrupts instead of the shell. If possible, use a shell running in another window.

If you execute programs that misbehave you may not be able to return to AXIOM. If this happens, you may have no other choice than to restart AXIOM and restore the environment via )history )restore, if possible.

**Also See:**

- o `)boot`
- o `)fin`
- o `)lisp`
- o `)pquit`
- o `)quit`

<sup>1</sup>

This command is in the list of `$noParseCommands` 7.1.3 which means that its arguments are passed verbatim. This will eventually result in a call to the function `handleNoParseCommands` 7.2.1

---

<sup>1</sup> “boot” (9 p 91) “fin” (19 p 149) “lisp” (25 p 223) “pquit” (28.2.1 p 230) “quit” (29.2.1 p 234)

## Chapter 38

# )trace Command

### 38.1 trace man page

*<trace.help>*≡

=====

A.26. )trace

=====

User Level Required: interpreter

Command Syntax:

- )trace
- )trace )off
  
- )trace function [options]
- )trace constructor [options]
- )trace domainOrPackage [options]

where options can be one or more of

- )after S-expression
- )before S-expression
- )break after
- )break before
- )cond S-expression
- )count
- )count n
- )depth n
- )local op1 [... opN]

- )nonquietly
- )nt
- )off
- )only listOfDataToDisplay
- )ops
- )ops op1 [... opN ]
- )restore
- )stats
- )stats reset
- )timer
- )varbreak
- )varbreak var1 [... varN ]
- )vars
- )vars var1 [... varN ]
- )within executingFunction

#### Command Description:

This command is used to trace the execution of functions that make up the AXIOM system, functions defined by users, and functions from the system library. Almost all options are available for each type of function but exceptions will be noted below.

To list all functions, constructors, domains and packages that are traced, simply issue

```
)trace
```

To untrace everything that is traced, issue

```
)trace )off
```

When a function is traced, the default system action is to display the arguments to the function and the return value when the function is exited. Note that if a function is left via an action such as a THROW, no return value will be displayed. Also, optimization of tail recursion may decrease the number of times a function is actually invoked and so may cause less trace information to be displayed. Other information can be displayed or collected when a function is traced and this is controlled by the various options. Most options will be of interest only to AXIOM system developers. If a domain or package is traced, the default action is to trace all functions exported.

Individual interpreter, lisp or boot functions can be traced by listing their names after )trace. Any options that are present must follow the functions to be traced.

```
)trace f
```

traces the function `f`. To untrace `f`, issue

```
)trace f )off
```

Note that if a function name contains a special character, it will be necessary to escape the character with an underscore

```
)trace _/D_,1
```

To trace all domains or packages that are or will be created from a particular constructor, give the constructor name or abbreviation after `)trace`.

```
)trace MATRIX
```

```
)trace List Integer
```

The first command traces all domains currently instantiated with `Matrix`. If additional domains are instantiated with this constructor (for example, if you have used `Matrix(Integer)` and `Matrix(Float)`), they will be automatically traced. The second command traces `List(Integer)`. It is possible to trace individual functions in a domain or package. See the `)ops` option below.

The following are the general options for the `)trace` command.

```
)break after
```

causes a Lisp break loop to be entered after exiting the traced function.

```
)break before
```

causes a Lisp break loop to be entered before entering the traced function.

```
)break
```

is the same as `)break before`.

```
)count
```

causes the system to keep a count of the number of times the traced function is entered. The total can be displayed with `)trace )stats` and cleared with `)trace )stats reset`.

```
)count n
```

causes information about the traced function to be displayed for the first `n` executions. After the `n`th execution, the function is untraced.

`)depth n`  
causes trace information to be shown for only `n` levels of recursion of the traced function. The command

`)trace fib )depth 10`

will cause the display of only 10 levels of trace information for the recursive execution of a user function `fib`.

`)math`  
causes the function arguments and return value to be displayed in the AXIOM monospace two-dimensional math format.

`)nonquietly`  
causes the display of additional messages when a function is traced.

`)nt`  
This suppresses all normal trace information. This option is useful if the `)count` or `)timer` options are used and you are interested in the statistics but not the function calling information.

`)off`  
causes untracing of all or specific functions. Without an argument, all functions, constructors, domains and packages are untraced. Otherwise, the given functions and other objects are untraced. To immediately retrace the untraced functions, issue `)trace )restore`.

`)only listOfDataToDisplay`  
causes only specific trace information to be shown. The items are listed by using the following abbreviations:

<code>a</code>	display all arguments
<code>v</code>	display return value
<code>1</code>	display first argument
<code>2</code>	display second argument
<code>15</code>	display the 15th argument, and so on

`)restore`  
causes the last untraced functions to be retraced. If additional options are present, they are added to those previously in effect.

`)stats`  
causes the display of statistics collected by the use of the `)count` and `)timer` options.

`)stats reset`

resets to 0 the statistics collected by the use of the `)count` and `)timer` options.

`)timer`

causes the system to keep a count of execution times for the traced function. The total can be displayed with `)trace )stats` and cleared with `)trace )stats reset`.

`)varbreak var1 [... varN]`

causes a Lisp break loop to be entered after the assignment to any of the listed variables in the traced function.

`)vars`

causes the display of the value of any variable after it is assigned in the traced function. Note that library code must have been compiled (see description of command `)compile` ) using the `)vartrace` option in order to support this option.

`)vars var1 [... varN]`

causes the display of the value of any of the specified variables after they are assigned in the traced function. Note that library code must have been compiled (see description of command `)compile` ) using the `)vartrace` option in order to support this option.

`)within executingFunction`

causes the display of trace information only if the traced function is called when the given `executingFunction` is running.

The following are the options for tracing constructors, domains and packages.

`)local [op1 [... opN]]`

causes local functions of the constructor to be traced. Note that to untrace an individual local function, you must use the fully qualified internal name, using the escape character `_` before the semicolon.

`)trace FRAC )local`

`)trace FRAC_;cancelGcd )off`

`)ops op1 [... opN]`

By default, all operations from a domain or package are traced when the domain or package is traced. This option allows you to specify that only particular operations should be traced. The command

`)trace Integer )ops min max _+ _-`

traces four operations from the domain `Integer`. Since `+` and `-` are special

characters, it is necessary to escape them with an underscore.

## Chapter 39

# )undo Command

### 39.1 undo man page

*<undo.help>*≡

=====

A.27. )undo

=====

User Level Required: interpreter

Command Syntax:

- )undo
- )undo integer
- )undo integer [option]
- )undo )redo

where option is one of

- )after
- )before

Command Description:

This command is used to restore the state of the user environment to an earlier point in the interactive session. The argument of an )undo is an integer which must designate some step number in the interactive session.

)undo n  
)undo n )after

These commands return the state of the interactive environment to that immediately after step *n*. If *n* is a positive number, then *n* refers to step number *n*. If *n* is a negative number, it refers to the *n*th previous command (that is, undoes the effects of the last *-n* commands).

A `)clear` all resets the `)undo` facility. Otherwise, an `)undo` undoes the effect of `)clear` with options properties, value, and mode, and that of a previous undo. If any such system commands are given between steps *n* and *n* + 1 (*n* > 0), their effect is undone for `)undo m` for any  $0 < m \leq n$ .

The command `)undo` is equivalent to `)undo -1` (it undoes the effect of the previous user expression). The command `)undo 0` undoes any of the above system commands issued since the last user expression.

`)undo n )before`

This command returns the state of the interactive environment to that immediately before step *n*. Any `)undo` or `)clear` system commands given before step *n* will not be undone.

`)undo )redo`

This command reads the file `redo.input`, created by the last `)undo` command. This file consists of all user input lines, excluding those backtracked over due to a previous `)undo`.

The command `)history )write` will eliminate the “undone” command lines of your program.

Also See:

o `)history`

1

## 39.2 Data Structures

`$frameRecord = [delta1, delta2, ... ]` where `delta(i)` contains changes in the “backwards” direction. Each `delta(i)` has the form `((var . proplist) ...)` where `proplist` denotes an ordinary proplist. For example, an entry of the form `((x (value) (mode (Integer)))) ...)` indicates that to undo 1 step, `x`’s value is cleared and its mode should be set to `(Integer)`.

A `delta(i)` of the form `(systemCommand . delta)` is a special delta indicating changes due to system commands executed between the last command and the current command. By recording these deltas separately, it is possible to undo to either BEFORE or AFTER the command. These special `delta(i)`s are given ONLY when a system command is given which alters the environment.

Note: `recordFrame('system)` is called before a command is executed, and `recordFrame('normal)` is called after (see `processInteractive1`). If no changes are found for former, no special entry is given.

The `$previousBindings` is a copy of the CAAR `$InteractiveFrame`. This is used to compute the `delta(i)`s stored in `$frameRecord`.

## 39.3 Functions

### 39.3.1 Initial Undo Variables

```
$undoFlag := true      --Default setting for undo is "on"
$frameRecord := nil    --Initial setting for frame record
$previousBindings := nil

<initvars>+≡
  (defvar |$undoFlag| t "t means we record undo information")
  (defvar |$frameRecord| nil "a list of value changes")
  (defvar |$previousBindings| nil "a copy of Interactive Frame info for undo")
  (defvar |$reportUndo| nil "t means we report the steps undo takes")
```

## 39.3.8 defun undoSteps

```

-- undoes m previous commands; if )before option, then undo one extra at end
--Example: if $IOindex now is 6 and m = 2 then general layout of $frameRecord,
-- after the call to recordFrame below will be:
-- (<change for systemcommands>
-- (<change for #5> <change for system commands>
-- (<change for #4> <change for system commands>
-- (<change for #3> <change for system commands>
-- <change for #2> <change for system commands>
-- <change for #1> <change for system commands>) where system
-- command entries are optional and identified by (systemCommand . change).
-- For a ")undo 3 )after", m = 2 and undoStep swill restore the environment
-- up to, but not including <change for #3>.
-- An "undo 3 )before" will additionally restore <change for #3>.
-- Thus, the later requires one extra undo at the end.

## Chapter 40

# )what Command

### 40.1 what man page

*<what.help>*≡

=====

A.28. )what

=====

User Level Required: interpreter

Command Syntax:

```
- )what categories pattern1 [pattern2 ...]
- )what commands  pattern1 [pattern2 ...]
- )what domains   pattern1 [pattern2 ...]
- )what operations pattern1 [pattern2 ...]
- )what packages  pattern1 [pattern2 ...]
- )what synonym   pattern1 [pattern2 ...]
- )what things    pattern1 [pattern2 ...]
- )apropos        pattern1 [pattern2 ...]
```

Command Description:

This command is used to display lists of things in the system. The patterns are all strings and, if present, restrict the contents of the lists. Only those items that contain one or more of the strings as substrings are displayed. For example,

)what synonym

displays all command synonyms,

```
)what synonym ver
```

displays all command synonyms containing the substring ‘‘ver’’,

```
)what synonym ver pr
```

displays all command synonyms containing the substring ‘‘ver’’ or the substring ‘‘pr’’. Output similar to the following will be displayed

```
----- System Command Synonyms -----
```

user-defined synonyms satisfying patterns:

```
ver pr
```

```
)apr ..... )what things
)apropos ..... )what things
)prompt ..... )set message prompt
)version ..... )lisp *yearweek*
```

Several other things can be listed with the )what command:

categories displays a list of category constructors.

commands displays a list of system commands available at your user-level. Your user-level is set via the )set userlevel command. To get a description of a particular command, such as ‘‘)what’’, issue )help what.

domains displays a list of domain constructors.

operations displays a list of operations in the system library.

It is recommended that you qualify this command with one or more patterns, as there are thousands of operations available. For example, say you are looking for functions that involve computation of eigenvalues. To find their names, try )what operations eig. A rather large list of operations is loaded into the workspace when this command is first issued. This list will be deleted when you clear the workspace via )clear all or )clear completely. It will be re-created if it is needed again.

packages displays a list of package constructors.

synonym lists system command synonyms.

things displays all of the above types for items containing the pattern strings as substrings. The command synonym )apropos is equivalent to )what things.

```

### 46.0.17 openserver (openserver)

This is a cover function for the C code used for communication interface.

```
<defun openserver>≡  
  (defun openserver (name)  
    (open_server name))
```

## Chapter 47

# Axiom Build-time Functions

### 47.0.18 defun spad-save

The **spad-save** function is just a cover function for more lisp system specific save functions. There is no standard name for saving a lisp image so we make one and conditionalize it at compile time.

This function is passed the name of an image that will be saved. The saved image contains all of the loaded functions.

This is used in the src/interp/Makefile.pamphlet in three places:

creating depsys, an image for compiling axiom.

Some of the Common Lisp code we compile uses macros which are assumed to be available at compile time. The **DEPSYS** image is created to contain the compile time environment and saved. We pipe compile commands into this environment to compile from Common Lisp to machine dependent code.

```
DEPSYS=${OBJ}/${SYS}/bin/depsys
```

creating savesys, an image for running axiom.

Once we've compile all of the Common Lisp files we fire up a clean lisp image called **LOADSYS**, load all of the final executable code and save it out as **SAVESYS**. The **SAVESYS** image is copied to the **\${MNT}/\${SYS}/bin** subdirectory and becomes the axiom executable image.

```
LOADSYS= ${OBJ}/${SYS}/bin/lisp
SAVESYS= ${OBJ}/${SYS}/bin/interpsys
AXIOMSYS= ${MNT}/${SYS}/bin/AXIOMsys
```

creating debugsys, an image with all interpreted functions loaded.

Occasionally we need to really get into the system internals. The best way to do this is to run almost all of the lisp code interpreted rather than compiled (note that cfuns.lisp and sockio.lisp still need to be loaded in compiled form as they depend on the loader to link with lisp internals). This image is nothing more than a load of the file src/interp/debugsys.lisp.pamphlet. If you need to make test modifications you can add code to that file and it will show up here.

```

DEBUGSYS=${OBJ}/${SYS}/bin/debugsys
<defun spad-save>≡
  (defun user::spad-save (save-file)
    (declare (special |$SpadServer| $openServerIfTrue))
    (setq |$SpadServer| nil)
    (setq $openServerIfTrue t)
    #+:AKCL
    (system::save-system save-file)
    #+:allegro
    (if (fboundp 'boot::restart)
        (excl::dumplisp :name save-file :restart-function #'boot::restart)
        (excl::dumplisp :name save-file))
    #+:Lucid
    (if (fboundp 'boot::restart)
        (sys::disksave save-file :restart-function #'boot::restart)
        (sys::disksave save-file))
    #+:CCL
    (preserve)
  )

```

## Chapter 48

# Exposure Groups

Exposure groups are a way of controlling the namespace available to the user. Certain algebra files are only useful for internal purposes but they contain functions have common names (like “map”. In order to separate the user visible functions from the internal functions the algebra files are collected into “exposure groups”. These large groups are grouped into sets in the file `exposed.lsp` which lives in the algebra subdirectory.

Exposure group information is kept in the local frame. For more information “The Frame Mechanism” ?? on page ??.

### 48.0.19 `loadExposureGroupData` (`loadExposureGroupData`)

This function is called from “restart” (4.3.2 p 11) at system startup time to load the file `exposed.lsp` to set up the exposure group information.

```
<defun loadExposureGroupData>≡
  (defun |loadExposureGroupData| ()
    (cond
      ((load "./exposed" :verbose nil :if-does-not-exist nil)
       '|done|)
      ((load (concat (getenv "AXIOM") "/algebra/exposed")
               :verbose nil :if-does-not-exist nil)
       '|done|)
      (t '|failed|) ))
```

## Chapter 49

# System Statistics

### 49.0.20 statisticsInitialization (statisticsInitialization)

## Chapter 53

# The Global Variables

### 53.1 Star Global Variables

NAME	SET	USE
<code>eof*</code>	<code>ncTopLevel</code>	
<code>features*</code>		restart
<code>package*</code>		restart
<code>standard-input*</code>		<code>ncIntLoop</code>
<code>standard-output*</code>		<code>ncIntLoop</code>
<code>top-level-hook*</code>	<code>set-restart-hook</code>	

#### 53.1.1 `*eof*`

The `*eof*` variable is set to `NIL` in `ncTopLevel`.

#### 53.1.2 `*features*`

The `*features*` variable from common lisp is tested for the presence of the `:unix` keyword. Apparently this controls the use of Saturn, a previous Axiom frontend. The Saturn frontend was never released as open source and so this test and the associated variables are probably not used.

#### 53.1.3 `*package*`

The `*package*` variable, from common lisp, is set in restart to the `BOOT` package where the interpreter lives.

#### 53.1.4 **\*standard-input\***

The **\*standard-input\*** common lisp variable is used to set the `curinstream` variable in `ncIntLoop`.

This variable is an argument to `serverReadLine` in the `intloopReadConsole` function.

#### 53.1.5 **\*standard-output\***

The **\*standard-output\*** common lisp variable is used to set the `curoutstream` variable in `ncIntLoop`.

#### 53.1.6 **\*top-level-hook\***

The **\*top-level-hook\*** common lisp variable contains the name of a function to invoke when an image is started. In our case it is called `restart`. This is the entry point to the Axiom interpreter.

## 53.2 Dollar Global Variables

NAME	SET	USE

\$nopus		SpadInterpretStream

### 53.2.1 `$boot`

The `$boot` variable is set to `NIL` in `ncTopLevel`.

### 53.2.2 `coerceFailure`

The `coerceFailure` symbol is a catch tag used in `runspad` to catch an exit from `ncTopLevel`.

### 53.2.3 `$current-directory`

This is set to the value returned by the `get-current-directory` function in “restart” (4.3.2 p 11). It is set to the argument of the `reroot` function.

So during execute both `$current-directory` and `$spadroot` reflect the value of the AXIOM shell variable.

### 53.2.4 `$currentLine`

The `$currentLine` line is set to `NIL` in restart. It is used in `removeUndoLines` in the undo mechanism.

### 53.2.5 `$defaultMsgDatabaseName`

The `$defaultMsgDatabaseName` is the absolute path to the `s2-us.msgs` file which contains all of the english language messages output by the system.

### 53.2.6 `$directory-list`

The `$directory-list` is a list of absolute directory names. These names are made absolute by mapping the `make-absolute-filename` over the variable `$relative-directory-list`.

### 53.2.7 `$displayStartMsgs`

The `$displayStartMsgs` variable is used in restart but is not set so this is likely a bug.

### 53.2.8 `$e`

The `$e` variable is set to the value of `$InteractiveFrame` which is set in restart to the value of the call to the `makeInitialModemapFrame` function. This function simply returns a copy of the variable `$InitialModemapFrame`.

Thus `$e` is a copy of the variable `$InitialModemapFrame`.

This variable is used in the undo mechanism.

### 53.2.9 `$erMsgToss`

The `$erMsgToss` variable is set to `NIL` in `SpadInterpretStream`.

### 53.2.10 `$fn`

The `$fn` variable is set in `SpadInterpretStream`. It is set to the second argument which is a list. It appears that this list has the same structure as an argument to the `LispVM rdefiostream` function.

### 53.2.11 `$frameRecord`

`$frameRecord = [delta1, delta2, ...]` where `delta(i)` contains changes in the “backwards” direction. Each `delta(i)` has the form `((var . proplist)...) where proplist denotes an ordinary proplist. For example, an entry of the form ((x (value) (mode (Integer)))) indicates that to undo 1 step, x’s value is cleared and its mode should be set to (Integer).`

A `delta(i)` of the form `(systemCommand . delta)` is a special delta indicating changes due to system commands executed between the last command and the current command. By recording these deltas separately, it is possible to undo to either BEFORE or AFTER the command. These special `delta(i)`s are given ONLY when a system command is given which alters the environment.

Note: `recordFrame('system)` is called before a command is executed, and `recordFrame('normal)` is called after (see `processInteractive1`). If no changes are found for former, no special entry is given.

This is part of the undo mechanism.

### 53.2.12 `$genValue`

If the `$genValue` variable is true then evaluate generated code, otherwise leave code unevaluated. If `$genValue` is false then we are compiling. This variable is only defined and used locally.

```
<initvars>+≡
  (defvar |$genValue| nil "evaluate generated code if true")
```

### 53.2.13 \$HiFiAccess

The `$HiFiAccess` is set by `initHist` to `T`. It is a flag used by the history mechanism to record whether the history function is currently on. It can be reset by using the `axiom` command

```
)history off
```

It appears that the name means “History File Access”.

The `$HiFiAccess` variable is used by `historySpad2Cmd` to check whether history is turned on. `T` means it is, `NIL` means it is not.

### 53.2.14 \$HistList

The `$HistList` variable is set by `initHistList` to an initial value of `NIL` elements. The last element of the list is smashed to point to the first element to make the list circular. This is a circular list of length `$HistListLen`.

### 53.2.15 \$HistListAct

The `$HistListAct` variable is set by `initHistList` to 0. This variable holds the actual number of elements in the history list. This is the number of “undoable” steps.

### 53.2.16 \$HistListLen

The `$HistListLen` variable is set by `initHistList` to 20. This is the length of a circular list maintained in the variable `$HistList`.

### 53.2.17 \$HistRecord

The `$HistRecord` variable is set by `initHistList` to `NIL`. `$HistRecord` collects the input line, all variable bindings and the output of a step, before it is written to the file named by the function `histFileName`.

### 53.2.18 \$historyFileType

The `$historyFileType` is set at load time by a call to `initvars` to a value of “axh”. It appears that this is intended to be used as a filetype extension. It is part of the history mechanism. It is used in `makeHistFileName` as part of the history file name.

### 53.2.19 `$inclAssertions`

The `$inclAssertions` is set in the function `SpadInterpretStream` to the list (`aix` —CommonLisp—)

### 53.2.20 `$internalHistoryTable`

The `$internalHistoryTable` variable is set at load time by a call to `initvars` to a value of `NIL`. It is part of the history mechanism.

### 53.2.21 `$interpreterFrameName`

The `$interpreterFrameName` variable, set in `initializeInterpreterFrameRing` to the constant `initial` to indicate that this is the initial (default) frame.

Frames are structures that capture all of the variables defined in a session. There can be multiple frames and the user can freely switch between them. Frames are kept in a ring data structure so you can move around the ring.

### 53.2.22 `$interpreterFrameRing`

The `$interpreterFrameRing` is set to a pair whose `car` is set to the result of `emptyInterpreterFrame`

### 53.2.23 `$InitialModemapFrame`

This variable is copied and returned by the function `makeInitialModemapFrame`. There is no initial value so this is probably a bug.

### 53.2.24 `$inLispVM`

The `$inLispVM` is set to `NIL` in `spad`. `LispVM` is a non-common lisp that runs on IBM/370 mainframes. This is probably dead code. It appears that this list has the same structure as an argument to the `LispVM rdefiostream` function.

### 53.2.25 `$InteractiveFrame`

The `$InteractiveFrame` is set in `restart` to the value of the call to the `makeInitialModemapFrame` function. This function simply returns a copy of the variable `$InitialModemapFrame`

### 53.2.26 `$intRestart`

The `$intRestart` variable is used in `intloop` but has no value. This is probably a bug. While the variable's value is unchanged the system will continually reenter the `SpadInterpretStream` function.

### 53.2.27 `$intTopLevel`

The `$intTopLevel` is a catch tag. Throwing to this tag which is caught in the `intloop` will restart the `SpadInterpretStream` function.

### 53.2.28 `$IOindex`

The `$IOindex` index variable is set to 1 in `restart`. This variable is used in the `historySpad2Cmd` function in the history mechanism. It is set in the `removeUndoLines` function in the undo mechanism.

This is used in the undo mechanism in function `undoCount` to compute the number of undos. You can't undo more actions than have already happened.

### 53.2.29 `$lastPos`

The `$lastPos` variable is set in `SpadInterpretStream` to the value of the `$npos` variable. Since `$npos` appears to have no value this is likely a bug.

### 53.2.30 `$libQuiet`

The `$libQuiet` variable is set to the third argument of the `SpadInterpretStream` function. This is passed from `intloop` with the value of `T`. This variable appears to be intended to control the printing of library loading messages which would need to be suppressed if input was coming from a file.

### 53.2.31 `$library-directory-list`

The `$library-directory-list` variable is set by `reroot` by mapping the function `make-absolute-filename` across the `$relative-library-directory-list` variable which is not yet set so this is probably a bug.

### 53.2.32 `$msgDatabaseName`

The `$msgDatabaseName` is set to `NIL` in `reroot`.

### 53.2.33 `$ncMsgList`

The `$ncMsgList` is set to NIL in `SpadInterpretStream`.

### 53.2.34 `$newcompErrorCount`

The `$newcompErrorCount` is set to 0 in `SpadInterpretStream`.

### 53.2.35 `$newcompMode`

The `$newcompMode` is set to NIL in `SpadInterpretStream`.

### 53.2.36 `$newspad`

The `$newspad` is set to T in `ncTopLevel`.

### 53.2.37 `$nopus`

The `$nopus` variable is used in `SpadInterpretStream` but does not appear to have a value and is likely a bug.

### 53.2.38 `$oldHistoryFileName`

The `$oldHistoryFileName` is set at load time by a call to `initvars` to a value of "last". It is part of the history mechanism. It is used in the function `oldHistoryFileName` and `restoreHistory`.

### 53.2.39 `$okToExecuteMachineCode`

The `$okToExecuteMachineCode` is set to T in `SpadInterpretStream`.

### 53.2.40 `$options`

The `$options` variable is tested by the history function. If it is NIL then output the message

```
You have not used the correct syntax for the history command.  
Issue )help history for more information.
```

The `$options` variable is tested in the `historySpad2Cmd` function. It appears to record the options that were given to a `spad` command on the input line. The function `selectOptionLC` appears to take a list of options to scan.

This variable is not yet set and is probably a bug.

#### 53.2.41 `$previousBindings`

The `$previousBindings` is a copy of the CAAR `$InteractiveFrame`. This is used to compute the delta(i)s stored in `$frameRecord`. This is part of the undo mechanism.

#### 53.2.42 `printLoadMsgs` (`printLoadMsgs`)

The `$printLoadMsgs` variable is set to T in restart.

#### 53.2.43 `$PrintCompilerMessageIfTrue`

The `$PrintCompilerMessageIfTrue` variable is set to NIL in spad.

#### 53.2.44 `$openServerIfTrue`

The `$openServerIfTrue` is tested in restart before it has been set (and is thus a bug). It appears to control whether the interpreter will be used as an open server, probably for OpenMath use.

If an open server is not requested then this variable to NIL

#### 53.2.45 `$relative-directory-list`

The `$relative-directory-list` is used in reroot to create `$directory-list` which is a list of absolute directory names. It is not yet set and is probably a bug.

#### 53.2.46 `$relative-library-directory-list`

The `$relative-library-directory-list` is used in reroot to create a list of absolute directory names from `$library-directory-list` (which is It is not yet set and is probably a bug).

#### 53.2.47 `$reportUndo`

The `$reportUndo` variable is used in diffAlist. It was not normally bound but has been set to T in initvars. If the variable is set to T then we call reportUndo.

It is part of the undo mechanism.

### 53.2.48 `$spadroot`

The `$spadroot` variable is the internal name for the AXIOM shell variable.

The `$spadroot` variable is set in `reroot` to the value of the argument. The argument is expected to be a directory name.

The `$spadroot` variable is tested in `initroot`.

The `$spadroot` variable is used by the function `make-absolute-filename`. It concatenates this variable to the front of a relative pathname to make it absolute.

### 53.2.49 `$spad`

The `$spad` variable is set to `T` in `ncTopLevel`.

### 53.2.50 `$SpadServer`

If an open server is not requested then this variable to `T`. It has no value before this time (and is thus a bug).

### 53.2.51 `$SpadServerName`

The `$SpadServerName` is passed to the `openServer` function, if the function exists.

### 53.2.52 `$systemCommandFunction`

The `$systemCommandFunction` is set in `SpadInterpretStream` to point to the function `InterpExecuteSpadSystemCommand`.

### 53.2.53 `top_level`

The `top_level` symbol is a catch tag used in `runspad` to catch an exit from `ncTopLevel`.

### 53.2.54 `$quitTag`

The `$quitTag` is used as a variable in a catch block. It appears that it can be thrown somewhere below `ncTopLevel`.

### 53.2.55 `$useInternalHistoryTable`

The `$useInternalHistoryTable` variable is set at load time by a call to `initvars` to a value of `NIL`. It is part of the history mechanism.

**53.2.56 \$undoFlag**

The `$undoFlag` is used in `recordFrame` to decide whether to do undo recording. It is initially set to T in `initvars`. This is part of the undo mechanism.
