++ References:
++ Description:
++   In this package F is a framed algebra over the integers (typically
++   \spad{F = Z[a]} for some algebraic integer a).  The package provides
++   functions to compute the integral closure of Z in the quotient
++   quotient field of F.
NumberFieldIntegralBasis(UP,F): Exports == Implementation where
  UP : UnivariatePolynomialCategory Integer
  F  : FramedAlgebra(Integer,UP)

++ Author: Yurij Baransky
++ Date Created: October 90
++ Date Last Updated: October 90
++ Basic Operations:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ This package is a suite of functions for the numerical integration of an
++ ordinary differential equation of n variables:
++
++         \center{dy/dx = f(y,x)\space{5}y is an n-vector}
++
++ \par All the routines are based on a 4-th order Runge-Kutta kernel.
++ These routines generally have as arguments:
++ n, the number of dependent variables;
++ x1, the initial point;
++ h, the step size;
++ y, a vector of initial conditions of length n which upon exit contains the sol
++ \spad{derivs}, a function which computes the right hand side of the
++ ordinary differential equation: \spad{derivs(dydx,y,x)} computes \spad{dydx},
++ a vector which contains the derivative information.
++
```

```
++ \par In order of increasing complexity:\begin{items}
++
++ \item \spad{rk4(y,n,x1,h,derivs)} advances the solution vector to
++ \spad{x1 + h} and return the values in y.
++
++ \item \spad{rk4(y,n,x1,h,derivs,t1,t2,t3,t4)} is the same as
++ \spad{rk4(y,n,x1,h,derivs)} except that you must provide 4 scratch
++ arrays t1-t4 of size n.
++
++ \item Starting with y at x1, \spad{rk4f(y,n,x1,x2,ns,derivs)}
++ uses \spad{ns} fixed
++ steps of a 4-th order Runge-Kutta integrator to advance the
++ solution vector to x2 and return the values in y.
++ Argument x2, is the final point, and
++ \spad{ns}, the number of steps to take.
++
++ \item \spad{rk4qc(y,n,x1,step,eps,yscal,derivs)} takes a 5-th order
++ Runge-Kutta step with monitoring
++ of local truncation to ensure accuracy and adjust stepsize.
++ The function takes two half steps and one full step and scales
++ the difference in solutions at the final point. If the error is
++ within \spad{eps}, the step is taken and the result is returned.
++ If the error is not within \spad{eps}, the stepsize if decreased
++ and the procedure is tried again until the desired accuracy is
++ reached. Upon input, an trial step size must be given and upon
++ return, an estimate of the next step size to use is returned as
++ well as the step size which produced the desired accuracy.
++ The scaled error is computed as
++ \center{\spad{error = MAX(ABS((y2steps(i) - y1step(i))/yscal(i)))}}
++ and this is compared against \spad{eps}. If this is greater
++ than \spad{eps}, the step size is reduced accordingly to
++ \center{\spad{hnew = 0.9 * hdid * (error/eps)**(-1/4)}}
++ If the error criterion is satisfied, then we check if the
++ step size was too fine and return a more efficient one. If
++ \spad{error > \spad{eps} * (6.0E-04)} then the next step size should be
++ \center{\spad{hnext = 0.9 * hdid * (error/\spad{eps})**(-1/5)}}
++ Otherwise \spad{hnext = 4.0 * hdid} is returned.
++ A more detailed discussion of this and related topics can be
++ found in the book "Numerical Recipies" by W.Press, B.P. Flannery,
++ S.A. Teukolsky, W.T. Vetterling published by Cambridge University Press.
++ Argument \spad{step} is a record of 3 floating point
++ numbers \spad{(try , did , next)},
++ \spad{eps} is the required accuracy,
++ \spad{yscal} is the scaling vector for the difference in solutions.
++ On input, \spad{step.try} should be the guess at a step
++ size to achieve the accuracy.
```

```
++ On output, \spad{step.did} contains the step size which achieved the
++ accuracy and \spad{step.next} is the next step size to use.
++
++ \item \spad{rk4qc(y,n,x1,step,eps,yscal,derivs,t1,t2,t3,t4,t5,t6,t7)} is the
++ same as \spad{rk4qc(y,n,x1,step,eps,yscal,derivs)} except that the user
++ must provide the 7 scratch arrays \spad{t1-t7} of size n.
++
++ \item \spad{rk4a(y,n,x1,x2,eps,h,ns,derivs)}
++ is a driver program which uses \spad{rk4qc} to integrate n ordinary
++ differential equations starting at x1 to x2, keeping the local
++ truncation error to within \spad{eps} by changing the local step size.
++ The scaling vector is defined as
++ \center{\spad{yscal(i) = abs(y(i)) + abs(h*dydx(i)) + tiny}}
++ where \spad{y(i)} is the solution at location x, \spad{dydx} is the
++ ordinary differential equation's right hand side, h is the current
++ step size and \spad{tiny} is 10 times the
++ smallest positive number representable.
++ The user must supply an estimate for a trial step size and
++ the maximum number of calls to \spad{rk4qc} to use.
++ Argument x2 is the final point,
++ \spad{eps} is local truncation,
++ \spad{ns} is the maximum number of call to \spad{rk4qc} to use.
++ \end{items}

++ Author: Yurij A. Baransky
++ Date Created: October 90
++ Date Last Updated: October 90
++ Basic Operations:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ This suite of routines performs numerical quadrature using
++ algorithms derived from the basic trapezoidal rule. Because
++ the error term of this rule contains only even powers of the
++ step size (for open and closed versions), fast convergence
++ can be obtained if the integrand is sufficiently smooth.
++
++ Each routine returns a Record of type TrapAns, which contains\indent{3}
++ \newline value (\spadtype{Float}):\tab{20}  estimate of the integral
++ \newline error (\spadtype{Float}):\tab{20}  estimate of the error in the computation
++ \newline totalpts (\spadtype{Integer}):\tab{20} total number of function evaluations
++ \newline success (\spadtype{Boolean}):\tab{20} if the integral was computed within the us
++ \indent{0}\indent{0}
++ To produce this estimate, each routine generates an internal
++ sequence of sub-estimates, denoted by {\em S(i)}, depending on the
```

```
++ routine, to which the various convergence criteria are applied.
++ The user must supply a relative accuracy, \spad{eps_r}, and an absolute
++ accuracy, \spad{eps_a}. Convergence is obtained when either
++ \center{\spad{ABS(S(i) - S(i-1)) < eps_r * ABS(S(i-1))}}
++ \center{or    \spad{ABS(S(i) - S(i-1)) < eps_a}}
++ are true statements.
++
++ The routines come in three families and three flavors:
++ \newline\tab{3} closed:\tab{20}romberg,\tab{30}simpson,\tab{42}trapezoidal
++ \newline\tab{3} open:  \tab{20}rombergo,\tab{30}simpsono,\tab{42}trapezoidalo
++ \newline\tab{3} adaptive closed:\tab{20}aromberg,\tab{30}asimpson,\tab{42}atra
++ \par
++ The {\em S(i)} for the trapezoidal family is the value of the
++ integral using an equally spaced absicca trapezoidal rule for
++ that level of refinement.
++ \par
++ The {\em S(i)} for the simpson family is the value of the integral
++ using an equally spaced absicca simpson rule for that level of
++ refinement.
++ \par
++ The {\em S(i)} for the romberg family is the estimate of the integral
++ using an equally spaced absicca romberg method. For
++ the \spad{i}-th level, this is an appropriate combination of all the
++ previous trapezodial estimates so that the error term starts
++ with the \spad{2*(i+1)} power only.
++ \par
++ The three families come in a closed version, where the formulas
++ include the endpoints, an open version where the formulas do not
++ include the endpoints and an adaptive version, where the user
++ is required to input the number of subintervals over which the
++ appropriate closed family integrator will apply with the usual
++ convergence parmeters for each subinterval. This is useful
++ where a large number of points are needed only in a small fraction
++ of the entire domain.
++ \par
++ Each routine takes as arguments:
++ \newline f\tab{10} integrand
++ \newline a\tab{10} starting point
++ \newline b\tab{10} ending point
++ \newline \spad{eps_r}\tab{10} relative error
++ \newline \spad{eps_a}\tab{10} absolute error
++ \newline \spad{nmin} \tab{10} refinement level when to start checking for conv
++ \newline \spad{nmax} \tab{10} maximum level of refinement
++ \par
++ The adaptive routines take as an additional parameter
++ \newline \spad{nint}\tab{10} the number of independent intervals to apply a cl
```

```
++  family integrator of the same name.
++ \par Notes:
++ \newline Closed family level i uses \spad{1 + 2**i} points.
++ \newline Open family level i uses \spad{1 + 3**i} points.

   aromberg     : (F -> F,F,F,F,F,I,I,I) -> TrapAns
     ++ aromberg(fn,a,b,epsrel,epsabs,nmin,nmax,nint)
     ++ uses the adaptive romberg method to numerically integrate function
     ++ \spad{fn} over the closed interval from \spad{a} to \spad{b},
     ++ with relative accuracy \spad{epsrel} and absolute accuracy
     ++ \spad{epsabs}, with the refinement levels for convergence checking
     ++ vary from \spad{nmin} to \spad{nmax}, and where \spad{nint}
     ++ is the number of independent intervals to apply the integrator.
     ++ The value returned is a record containing the value of the integral,
     ++ the estimate of the error in the computation, the total number of
     ++ function evaluations, and either a boolean value which is true if
     ++ the integral was computed within the user specified error criterion.
     ++ See \spadtype{NumericalQuadrature} for details.
   asimpson     : (F -> F,F,F,F,F,I,I,I) -> TrapAns
     ++ asimpson(fn,a,b,epsrel,epsabs,nmin,nmax,nint) uses the
     ++ adaptive simpson method to numerically integrate function \spad{fn}
     ++ over the closed interval from \spad{a} to \spad{b}, with relative
     ++ accuracy \spad{epsrel} and absolute accuracy \spad{epsabs}, with the
     ++ refinement levels for convergence checking vary from \spad{nmin}
     ++ to \spad{nmax}, and where \spad{nint} is the number of independent
     ++ intervals to apply the integrator. The value returned is a record
     ++ containing the value of the integral, the estimate of the error in
     ++ the computation, the total number of function evaluations, and
     ++ either a boolean value which is true if the integral was computed
     ++ within the user specified error criterion.
     ++ See \spadtype{NumericalQuadrature} for details.
   atrapezoidal : (F -> F,F,F,F,F,I,I,I) -> TrapAns
     ++ atrapezoidal(fn,a,b,epsrel,epsabs,nmin,nmax,nint) uses the
     ++ adaptive trapezoidal method to numerically integrate function
     ++ \spad{fn} over the closed interval from \spad{a} to \spad{b}, with
```

```
  ++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
  ++ with the refinement levels for convergence checking vary from
  ++ \spad{nmin} to \spad{nmax}, and where \spad{nint} is the number
  ++ of independent intervals to apply the integrator. The value returned
  ++ is a record containing the value of the integral, the estimate of
  ++ the error in the computation, the total number of function
  ++ evaluations, and either a boolean value which is true if
  ++ the integral was computed within the user specified error criterion.
  ++ See \spadtype{NumericalQuadrature} for details.
romberg      : (F -> F,F,F,F,F,I,I) -> TrapAns
  ++ romberg(fn,a,b,epsrel,epsabs,nmin,nmax) uses the romberg
  ++ method to numerically integrate function \spadvar{fn} over the closed
  ++ interval \spad{a} to \spad{b}, with relative accuracy \spad{epsrel}
  ++ and absolute accuracy \spad{epsabs}, with the refinement levels
  ++ for convergence checking vary from \spad{nmin} to \spad{nmax}.
  ++ The value returned is a record containing the value
  ++ of the integral, the estimate of the error in the computation, the
  ++ total number of function evaluations, and either a boolean value
  ++ which is true if the integral was computed within the user specified
  ++ error criterion. See \spadtype{NumericalQuadrature} for details.
simpson      : (F -> F,F,F,F,F,I,I) -> TrapAns
  ++ simpson(fn,a,b,epsrel,epsabs,nmin,nmax) uses the simpson
  ++ method to numerically integrate function \spad{fn} over the closed
  ++ interval \spad{a} to \spad{b}, with
  ++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
  ++ with the refinement levels for convergence checking vary from
  ++ \spad{nmin} to \spad{nmax}. The value returned
  ++ is a record containing the value of the integral, the estimate of
  ++ the error in the computation, the total number of function
  ++ evaluations, and either a boolean value which is true if
  ++ the integral was computed within the user specified error criterion.
  ++ See \spadtype{NumericalQuadrature} for details.
trapezoidal  : (F -> F,F,F,F,F,I,I) -> TrapAns
  ++ trapezoidal(fn,a,b,epsrel,epsabs,nmin,nmax) uses the
  ++ trapezoidal method to numerically integrate function \spadvar{fn} over
  ++ the closed interval \spad{a} to \spad{b}, with relative accuracy
  ++ \spad{epsrel} and absolute accuracy \spad{epsabs}, with the
  ++ refinement levels for convergence checking vary
  ++ from \spad{nmin} to \spad{nmax}. The value
  ++ returned is a record containing the value of the integral, the
  ++ estimate of the error in the computation, the total number of
  ++ function evaluations, and either a boolean value which is true
  ++ if the integral was computed within the user specified error criterion.
  ++ See \spadtype{NumericalQuadrature} for details.
rombergo     : (F -> F,F,F,F,F,I,I) -> TrapAns
  ++ rombergo(fn,a,b,epsrel,epsabs,nmin,nmax) uses the romberg
```

```
      ++ method to numerically integrate function \spad{fn} over
      ++ the open interval from \spad{a} to \spad{b}, with
      ++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
      ++ with the refinement levels for convergence checking vary from
      ++ \spad{nmin} to \spad{nmax}. The value returned
      ++ is a record containing the value of the integral, the estimate of
      ++ the error in the computation, the total number of function
      ++ evaluations, and either a boolean value which is true if
      ++ the integral was computed within the user specified error criterion.
      ++ See \spadtype{NumericalQuadrature} for details.
    simpsono     : (F -> F,F,F,F,F,I,I) -> TrapAns
      ++ simpsono(fn,a,b,epsrel,epsabs,nmin,nmax) uses the
      ++ simpson method to numerically integrate function \spad{fn} over
      ++ the open interval from \spad{a} to \spad{b}, with
      ++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
      ++ with the refinement levels for convergence checking vary from
      ++ \spad{nmin} to \spad{nmax}. The value returned

++ Description:
++ In this package K is a finite field, R is a ring of univariate
++ polynomials over K, and F is a monogenic algebra over R.
++ We require that F is monogenic, i.e. that \spad{F = K[x,y]/(f(x,y))},
++ because the integral basis algorithm used will factor the polynomial
++ \spad{f(x,y)}.  The package provides a function to compute the integral
++ closure of R in the quotient field of F as well as a function to compute
++ a "local integral basis" at a specific prime.

++ This package completely solves a parametric linear system of equations
++ by decomposing the set of all parametric values for which the linear
++ system is consistent into a union of quasi-algebraic  sets (which need
++ not be irredundant, but most of the time is). Each quasi-algebraic
++ set is described by a list of polynomials that vanish on the set, and
++ a list of polynomials that vanish at no point of the set.
++ For each quasi-algebraic set, the solution of the linear system
++ is given, as a particular solution and  a basis of the homogeneous
++ system.
++ The parametric linear system should be given in matrix form, with
++ a coefficient matrix and a right hand side vector. The entries
++ of the coefficient matrix and right hand side vector should be
++ polynomials in the parametric variables, over a Euclidean domain
++ of characteristic zero.
++
++ If the system is homogeneous, the right hand side need not be given.
++ The right hand side can also be  replaced by an indeterminate vector,
++ in which case, the conditions required for consistency will also be
++ given.
++
++ The package has other facilities for saving results to external
++ files, as well as solving the system for a specified minimum rank.
++ Altogether there are 12 mode maps for psolve, as explained below.
```

```
-- modified to conform with new runtime system 06/04/90
-- updated with comments for MB, 02/16/94
-- also cleaned up some unnecessary arguments in regime routine
--
-- MB: In order to allow the rhs to be indeterminate, while working
-- mainly with the parametric variables on the lhs (less number of
-- variables), certain conversions of internal representation from
-- GR to Polynomial R and Fraction Polynomial R are done.  At the time
-- of implementation, I thought that this may be more efficient.  I
-- have not done any comparison since that requires rewriting the
-- package.  My own application needs to call this package quite often,
-- and most computations involves only polynomials in the parametric
-- variables.

-- The 12 modes of psolve are probably not all necessary.  Again, I
-- was thinking that if there are many regimes and many ranks, then
-- the output is quite big, and it may be nice to be able to save it
-- and read the results in later to continue computing rather than
-- recomputing.  Because of the combinatorial nature of the algorithm
-- (computing all subdeterminants!), it does not take a very big matrix
-- to get into many regimes.  But I now have second thoughts of this
-- design, since most of the time, the results are just intermediate,
-- passed to be further processed.  On the other hand, there is probably
-- no penalty in leaving the options as is.
```

-- MB: The following macros are data structures to store mostly
-- intermediate results
-- Rec stores a subdeterminant with corresponding row and column indices
-- Fgb is a Groebner basis for the ideal generated by the subdeterminants
--     of a given rank.
-- Linsys specifies a linearly independent system of a given system
--     assuming a given rank, using given row and column indices
-- Linsoln stores the solution to the parametric linear system as a basis
--     and a particular solution (for a given regime)
-- Rec2 stores the rank, and a list of subdeterminants of that rank,
--     and a Groebner basis for the ideal they generate.
-- Rec3 stores a regime and the corresponding solution; the regime is
--     given by a list of equations (eqzro) and one inequation (neqzro)
--     describing the quasi-algebraic set which is the regime; the
--     additional consistency conditions due to the rhs is given by wcond.
-- Ranksolns stores a list of regimes and their solutions, and the number
--     of regimes all together.
-- Rec8 (temporary) stores a quasi-algebraic set with an indication
-- whether it is empty (sysok = false) or not (sysok = true).

-- I think psolve should be renamed parametricSolve, or even
-- parametricLinearSolve.  On the other hand, may be just solve will do.
-- Please feel free to change it to conform with system conventions.
-- Most psolve routines return a list of regimes and solutions,
-- except those that output to file when the number of regimes is
-- returned instead.
-- This version has been tested on the pc version 1.608 March 13, 1992

++ Description: PartitionsAndPermutations contains
++ functions for generating streams of integer partitions,
++ and streams of sequences of integers
++ composed from a multi-set.
PartitionsAndPermutations: Exports == Implementation where
  I   ==> Integer
  L   ==> List
  ST  ==> Stream
  ST1 ==> StreamFunctions1
  ST2 ==> StreamFunctions2
  ST3 ==> StreamFunctions3

  Exports ==> with

    partitions: (I,I,I) -> ST L I
```

```
    ++\spad{partitions(p,l,n)} is the stream of partitions
    ++ of n whose number of parts is no greater than p
    ++ and whose largest part is no greater than l.
  partitions: I -> ST L I
    ++\spad{partitions(n)} is the stream of all partitions of n.
  partitions: (I,I) -> ST L I
    ++\spad{partitions(p,l)} is the stream of all
    ++ partitions whose number of
    ++ parts and largest part are no greater than p and l.
  conjugate: L I -> L I
    ++\spad{conjugate(pt)} is the conjugate of the partition pt.
  conjugates: ST L I -> ST L I
    ++\spad{conjugates(lp)} is the stream of conjugates of a stream
    ++ of partitions lp.
  shuffle: (L I,L I) -> ST L I
    ++\spad{shuffle(l1,l2)} forms the stream of all shuffles of l1
    ++ and l2, i.e. all sequences that can be formed from
    ++ merging l1 and l2.
  shufflein: (L I,ST L I) -> ST L I
    ++\spad{shufflein(l,st)} maps shuffle(l,u) on to all
    ++ members u of st, concatenating the results.
  sequences: (L I,L I) -> ST L I
    ++\spad{sequences(l1,l2)} is the stream of all sequences that
    ++ can be composed from the multiset defined from
    ++ two lists of integers l1 and l2.
    ++ For example,the pair \spad{([1,2,4],[2,3,5])} represents
    ++ multi-set with 1 \spad{2}, 2 \spad{3}'s, and 4 \spad{5}'s.
  sequences: L I -> ST L I
    ++ \spad{sequences([l0,l1,l2,..,ln])} is the set of
    ++  all sequences formed from
    ++ \spad{l0} 0's,\spad{l1} 1's,\spad{l2} 2's,...,\spad{ln} n's.
  permutations: I -> ST L I
    ++\spad{permutations(n)} is the stream of permutations
    ++ formed from \spad{1,2,3,...,n}.

==========================================================================
Permanent examples
==========================================================================

The package Permanent provides the function permanent for square
matrices.  The permanent of a square matrix can be computed in the
same way as the determinant by expansion of minors except that for the
permanent the sign for each element is 1, rather than being 1 if the
row plus column indices is positive and -1 otherwise.  This function
is much more difficult to compute efficiently than the determinant.
An example of the use of permanent is the calculation of the n-th
derangement number, defined to be the number of different possibilities
for n couples to dance but never with their own spouse.

Consider an n by n matrix with entries 0 on the diagonal and 1 elsewhere.
Think of the rows as one-half of each couple (for example, the males) and
the columns the other half.  The permanent of such a matrix gives the
desired derangement number.

  kn n ==
    r : MATRIX INT := new(n,n,1)
    for i in 1..n repeat
      r.i.i := 0
    r

Here are some derangement numbers, which you see grow quite fast.

  permanent(kn(5) :: SQMATRIX(5,INT))

  [permanent(kn(n) :: SQMATRIX(n,INT)) for n in 1..13]

++    Computer Science Press, 1985.
++ Description:
++  Permanent implements the functions {\em permanent}, the
++  permanent for square matrices.
Permanent(n : PositiveInteger, R : Ring with commutative("*")):
 public == private where
  I  ==> Integer
  L  ==> List
  V  ==> Vector
  SM  ==> SquareMatrix(n,R)
  VECTPKG1 ==> VectorPackage1(I)
  NNI ==> NonNegativeInteger
  PI ==> PositiveInteger
  GRAY ==> GrayCode
```

```
public ==> with

  permanent:  SM  -> R
    ++ permanent(x) computes the permanent of a square matrix x.
    ++ The {\em permanent} is equivalent to
    ++ the \spadfun{determinant} except that coefficients have
    ++ no change of sign. This function
    ++ is much more difficult to compute than the
    ++ {\em determinant}. The formula used is by H.J. Ryser,
    ++ improved by [Nijenhuis and Wilf, Ch. 19].
    ++ Note: permanent(x) choose one of three algorithms, depending
    ++ on the underlying ring R and on n, the number of rows (and
    ++ columns) of x:\begin{items}
    ++ \item 1. if 2 has an inverse in R we can use the algorithm of
    ++    [Nijenhuis and Wilf, ch.19,p.158]; if 2 has no inverse,
    ++    some modifications are necessary:
    ++ \item 2. if {\em n > 6} and R is an integral domain with characteristic
    ++    different from 2 (the algorithm works if and only 2 is not a
    ++    zero-divisor of R and {\em characteristic()$R ^= 2},
    ++    but how to check that for any given R ?),
    ++    the local function {\em permanent2} is called;
    ++ \item 3. else, the local function {\em permanent3} is called
    ++    (works for all commutative rings R).
    ++ \end{items}

    phiCoord     : POINT -> R
      ++ phiCoord(pt) returns the third element of the point, pt,
      ++ although no assumptions are made as to the coordinate
      ++ system being used.  This function is defined for the
      ++ convenience of the user dealing with a spherical
      ++ coordinate system.
    color        : POINT -> R
      ++ color(pt) returns the fourth element of the point, pt,
      ++ although no assumptions are made with regards as to
      ++ how the components of higher dimensional points are
      ++ interpreted.  This function is defined for the
      ++ convenience of the user using specifically, color
      ++ to express a fourth dimension.
    hue : POINT -> R
      ++ hue(pt) returns the third element of the two dimensional point, pt,
      ++ although no assumptions are made with regards as to how the
      ++ components of higher dimensional points are interpreted. This
      ++ function is defined for the convenience of the user using
      ++ specifically, hue to express a third dimension.
    shade : POINT -> R
      ++ shade(pt) returns the fourth element of the two dimensional
      ++ point, pt, although no assumptions are made with regards as to
      ++ how the components of higher dimensional points are interpreted.
      ++ This function is defined for the convenience of the user using
      ++ specifically, shade to express a fourth dimension.

++ Description:
++ Groebner functions for P F
++   This package is an interface package to the groebner basis
++ package which allows you to compute groebner bases for polynomials
++ in either lexicographic ordering or total degree ordering refined
++ by reverse lex. The input is the ordinary polynomial type which
++ is internally converted to a type with the required ordering.
++ The resulting grobner basis is converted back to ordinary polynomials.
++ The ordering among the variables is controlled by an explicit list
++ of variables which is passed as a second argument. The coefficient
++ domain is allowed to be any gcd domain, but the groebner basis is
++ computed as if the polynomials were over a field.

++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++   This package computes multivariate polynomial gcd's using
++ a hensel lifting strategy. The contraint on the coefficient
++ domain is imposed by the lifting strategy. It is assumed that
++ the coefficient domain has the property that almost all specializations
++ preserve the degree of the gcd.

++ Description:
++ This package provides modest routines for polynomial system solving.
++ The aim of many of the operations of this package is to remove certain
++ factors in some polynomials in order to avoid unnecessary computations
++ in algorithms involving splitting techniques by partial factorization.
++ Version: 3

     removeRedundantFactors: LP -> LP
        ++ \axiom{removeRedundantFactors(lp)} returns \axiom{lq} such that if
        ++ \axiom{lp = [p1,...,pn]} and \axiom{lq = [q1,...,qm]}
        ++ then the product \axiom{p1*p2*...*pn} vanishes iff the product \axiom{
        ++ and the product of degrees of the \axiom{qi} is not greater than
        ++ the one of the \axiom{pj}, and no polynomial in \axiom{lq}
        ++ divides another polynomial in \axiom{lq}. In particular,
        ++ polynomials lying in the base ring \axiom{R} are removed.
        ++ Moreover, \axiom{lq} is sorted w.r.t \axiom{infRittWu?}.
        ++ Furthermore, if R is gcd-domain, the polynomials in \axiom{lq} are
        ++ pairwise without common non trivial factor.
     removeRedundantFactors: (P,P) -> LP
        ++ \axiom{removeRedundantFactors(p,q)} returns the same as
        ++ \axiom{removeRedundantFactors([p,q])}
     removeSquaresIfCan : LP -> LP
        ++ \axiom{removeSquaresIfCan(lp)} returns
        ++ \axiom{removeDuplicates [squareFreePart(p)$P for p in lp]}
        ++ if \axiom{R} is gcd-domain else returns \axiom{lp}.
```

```
unprotectedRemoveRedundantFactors: (P,P) -> LP
   ++ \axiom{unprotectedRemoveRedundantFactors(p,q)} returns the same as
   ++ \axiom{removeRedundantFactors(p,q)} but does assume that neither
   ++ \axiom{p} nor \axiom{q} lie in the base ring \axiom{R} and assumes that
   ++ \axiom{infRittWu?(p,q)} holds. Moreover, if \axiom{R} is gcd-domain,
   ++ then \axiom{p} and \axiom{q} are assumed to be square free.
removeRedundantFactors: (LP,P) -> LP
   ++ \axiom{removeRedundantFactors(lp,q)} returns the same as
   ++ \axiom{removeRedundantFactors(cons(q,lp))} assuming
   ++ that \axiom{removeRedundantFactors(lp)} returns \axiom{lp}
   ++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
   ++ by some some polynomial \axiom{qj} associated to \axiom{pj}.
removeRedundantFactors : (LP,LP) -> LP
   ++ \axiom{removeRedundantFactors(lp,lq)} returns the same as
   ++ \axiom{removeRedundantFactors(concat(lp,lq))} assuming
   ++ that \axiom{removeRedundantFactors(lp)} returns \axiom{lp}
   ++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
   ++ by some polynomial \axiom{qj} associated to \axiom{pj}.
removeRedundantFactors : (LP,LP,(LP -> LP)) -> LP
   ++ \axiom{removeRedundantFactors(lp,lq,remOp)} returns the same as
   ++ \axiom{concat(remOp(removeRoughlyRedundantFactorsInPols(lp,lq)),lq)}
   ++ assuming that \axiom{remOp(lq)} returns \axiom{lq} up to similarity.
certainlySubVariety? : (LP,LP) -> B
   ++ \axiom{certainlySubVariety?(newlp,lp)} returns true iff for every \axiom{p}
   ++ in \axiom{lp} the remainder of \axiom{p} by \axiom{newlp} using the division algo
   ++ of Groebner techniques is zero.
possiblyNewVariety? : (LP, List LP) -> B
   ++ \axiom{possiblyNewVariety?(newlp,llp)} returns true iff for every \axiom{lp}
   ++ in \axiom{llp} certainlySubVariety?(newlp,lp) does not hold.
probablyZeroDim?: LP -> B
   ++ \axiom{probablyZeroDim?(lp)} returns true iff the number of polynomials
   ++ in \axiom{lp} is not smaller than the number of variables occurring
   ++ in these polynomials.
selectPolynomials : ((P -> B),LP) -> Record(goodPols:LP,badPols:LP)
   ++ \axiom{selectPolynomials(pred?,ps)} returns \axiom{gps,bps} where
   ++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
   ++ such that \axiom{pred?(p)} holds and \axiom{bps} are the other ones.
selectOrPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
   ++ \axiom{selectOrPolynomials(lpred?,ps)} returns \axiom{gps,bps} where
   ++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
   ++ such that \axiom{pred?(p)} holds for some \axiom{pred?} in \axiom{lpred?}
   ++ and \axiom{bps} are the other ones.
selectAndPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
   ++ \axiom{selectAndPolynomials(lpred?,ps)} returns \axiom{gps,bps} where
   ++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
   ++ such that \axiom{pred?(p)} holds for every \axiom{pred?} in \axiom{lpred?}
```

```
   ++ and \axiom{bps} are the other ones.
quasiMonicPolynomials : LP -> Record(goodPols:LP,badPols:LP)
   ++ \axiom{quasiMonicPolynomials(lp)} returns \axiom{qmps,nqmps} where
   ++ \axiom{qmps} is a list of the quasi-monic polynomials in \axiom{lp}
   ++ and \axiom{nqmps} are the other ones.
univariate? : P -> B
   ++ \axiom{univariate?(p)} returns true iff \axiom{p} involves one and
   ++ only one variable.
univariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
   ++ \axiom{univariatePolynomials(lp)} returns \axiom{ups,nups} where
   ++ \axiom{ups} is a list of the univariate polynomials,
   ++ and \axiom{nups} are the other ones.
linear? : P -> B
   ++ \axiom{linear?(p)} returns true iff \axiom{p} does not lie
   ++ in the base ring \axiom{R} and has main degree \axiom{1}.
linearPolynomials : LP -> Record(goodPols:LP,badPols:LP)
   ++ \axiom{linearPolynomials(lp)} returns \axiom{lps,nlps} where
   ++ \axiom{lps} is a list of the linear polynomials in lp,
   ++ and  \axiom{nlps} are the other ones.
bivariate? : P -> B
   ++ \axiom{bivariate?(p)} returns true iff \axiom{p} involves two and
   ++ only two variables.
bivariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
   ++ \axiom{bivariatePolynomials(lp)} returns \axiom{bps,nbps} where
   ++ \axiom{bps} is a list of the bivariate polynomials,
   ++ and \axiom{nbps} are the other ones.
removeRoughlyRedundantFactorsInPols : (LP, LP) -> LP
   ++ \axiom{removeRoughlyRedundantFactorsInPols(lp,lf)} returns
   ++ \axiom{newlp}where \axiom{newlp} is obtained from \axiom{lp}
   ++ by removing in every polynomial \axiom{p} of \axiom{lp}
   ++ any occurence of a polynomial \axiom{f} in \axiom{lf}.
   ++ This may involve a lot of exact-quotients computations.
removeRoughlyRedundantFactorsInPols : (LP, LP,B) -> LP
   ++ \axiom{removeRoughlyRedundantFactorsInPols(lp,lf,opt)} returns
   ++ the same as \axiom{removeRoughlyRedundantFactorsInPols(lp,lf)}
   ++ if \axiom{opt} is \axiom{false} and if the previous operation
   ++ does not return any non null and constant polynomial,
   ++ else return \axiom{[1]}.
removeRoughlyRedundantFactorsInPol : (P,LP) -> P
   ++ \axiom{removeRoughlyRedundantFactorsInPol(p,lf)} returns the same as
   ++ removeRoughlyRedundantFactorsInPols([p],lf,true)
interReduce: LP -> LP
   ++ \axiom{interReduce(lp)} returns \axiom{lq} such that \axiom{lp}
   ++ and \axiom{lq} generate the same ideal and no polynomial
   ++ in \axiom{lq} is reducuble by the others in the sense
   ++ of Groebner bases. Since no assumptions are required
```

```
      ++ the result may depend on the ordering the reductions are
      ++ performed.
    roughBasicSet: LP -> Union(Record(bas:T,top:LP),"failed")
      ++ \axiom{roughBasicSet(lp)} returns the smallest (with Ritt-Wu
      ++ ordering) triangular set contained in \axiom{lp}.
    crushedSet: LP -> LP
      ++ \axiom{crushedSet(lp)} returns \axiom{lq} such that \axiom{lp} and
      ++ and \axiom{lq} generate the same ideal and no rough basic
      ++ sets reduce (in the sense of Groebner bases) the other
      ++ polynomials in \axiom{lq}.
    rewriteSetByReducingWithParticularGenerators : (LP,(P->B),((P,P)->B),((P,P)->P)) -> LP
      ++ \axiom{rewriteSetByReducingWithParticularGenerators(lp,pred?,redOp?,redOp)}
      ++ returns \axiom{lq} where \axiom{lq} is computed by the following
      ++ algorithm. Chose a basic set w.r.t. the reduction-test \axiom{redOp?}
      ++ among the polynomials satisfying property \axiom{pred?},
      ++ if it is empty then leave, else reduce the other polynomials by
      ++ this basic set w.r.t. the reduction-operation \axiom{redOp}.
      ++ Repeat while another basic set with smaller rank can be computed.
      ++ See code. If \axiom{pred?} is \axiom{quasiMonic?} the ideal is unchanged.
    rewriteIdealWithQuasiMonicGenerators : (LP,((P,P)->B),((P,P)->P)) -> LP
      ++ \axiom{rewriteIdealWithQuasiMonicGenerators(lp,redOp?,redOp)} returns
      ++ \axiom{lq} where \axiom{lq} and \axiom{lp} generate
      ++ the same ideal in \axiom{R^(-1) P} and \axiom{lq}
      ++ has rank not higher than the one of \axiom{lp}.
      ++ Moreover, \axiom{lq} is computed by reducing \axiom{lp}
      ++ w.r.t. some basic set of the ideal generated by
      ++ the quasi-monic polynomials in \axiom{lp}.
    if R has GcdDomain
    then
      squareFreeFactors : P -> LP
        ++ \axiom{squareFreeFactors(p)} returns the square-free factors of \axiom{p}
        ++ over \axiom{R}
      univariatePolynomialsGcds : LP -> LP
        ++ \axiom{univariatePolynomialsGcds(lp)} returns \axiom{lg} where
        ++ \axiom{lg} is a list of the gcds of every pair in \axiom{lp}
        ++ of univariate polynomials in the same main variable.
      univariatePolynomialsGcds : (LP,B) -> LP
        ++ \axiom{univariatePolynomialsGcds(lp,opt)} returns the same as
        ++ \axiom{univariatePolynomialsGcds(lp)} if \axiom{opt} is
        ++ \axiom{false} and if the previous operation does not return
        ++ any non null and constant polynomial, else return \axiom{[1]}.
      removeRoughlyRedundantFactorsInContents : (LP, LP) -> LP
        ++ \axiom{removeRoughlyRedundantFactorsInContents(lp,lf)} returns
        ++ \axiom{newlp}where \axiom{newlp} is obtained from \axiom{lp}
        ++ by removing in the content of every polynomial of \axiom{lp}
        ++ any occurence of a polynomial \axiom{f} in \axiom{lf}. Moreover,
```

```
        ++ squares over \axiom{R} are first removed in the content
        ++ of every polynomial of \axiom{lp}.
      removeRedundantFactorsInContents : (LP, LP) -> LP
        ++ \axiom{removeRedundantFactorsInContents(lp,lf)} returns \axiom{newlp}
        ++ where \axiom{newlp} is obtained from \axiom{lp} by removing
        ++ in the content of every polynomial of \axiom{lp} any non trivial
        ++ factor of any polynomial \axiom{f} in \axiom{lf}. Moreover,
        ++ squares over \axiom{R} are first removed in the content
        ++ of every polynomial of \axiom{lp}.
      removeRedundantFactorsInPols : (LP, LP) -> LP
        ++ \axiom{removeRedundantFactorsInPols(lp,lf)} returns \axiom{newlp}
        ++ where \axiom{newlp} is obtained from \axiom{lp} by removing
        ++ in every polynomial \axiom{p} of \axiom{lp} any non trivial
        ++ factor of any polynomial \axiom{f} in \axiom{lf}. Moreover,
        ++ squares over \axiom{R} are first removed in every
        ++ polynomial \axiom{lp}.
    if (R has EuclideanDomain) and (R has CharacteristicZero)
    then
      irreducibleFactors : LP -> LP
        ++ \axiom{irreducibleFactors(lp)} returns \axiom{lf} such that if
        ++ \axiom{lp = [p1,...,pn]} and \axiom{lf = [f1,...,fm]} then
        ++ \axiom{p1*p2*...*pn=0} means \axiom{f1*f2*...*fm=0}, and the \axiom{
        ++ are irreducible over \axiom{R} and are pairwise distinct.
      lazyIrreducibleFactors : LP -> LP
        ++ \axiom{lazyIrreducibleFactors(lp)} returns \axiom{lf} such that if
        ++ \axiom{lp = [p1,...,pn]} and \axiom{lf = [f1,...,fm]} then
        ++ \axiom{p1*p2*...*pn=0} means \axiom{f1*f2*...*fm=0}, and the \axiom{
        ++ are irreducible over \axiom{R} and are pairwise distinct.
        ++ The algorithm tries to avoid factorization into irreducible
        ++ factors as far as possible and makes previously use of gcd
        ++ techniques over \axiom{R}.
      removeIrreducibleRedundantFactors : (LP, LP) -> LP
        ++ \axiom{removeIrreducibleRedundantFactors(lp,lq)} returns the same
        ++ as \axiom{irreducibleFactors(concat(lp,lq))} assuming
        ++ that \axiom{irreducibleFactors(lp)} returns \axiom{lp}
        ++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
        ++ by some polynomial \axiom{qj} associated to \axiom{pj}.

)abbrev package SOLVEFOR PolynomialSolveByFormulas
--  Current fields with "**": (%, RationalNumber) -> % are
--     ComplexFloat, RadicalExtension(K) and RationalRadical
--  SMW June 86, BMT Sept 93
++ Description:
++ This package factors the formulas out of the general solve code,
++ allowing their recursive use over different domains.
++ Care is taken to introduce few radicals so that radical extension
++ domains can more easily simplify the results.

++ References:
++ Description:
++ This package computes square-free decomposition of multivariate
++ polynomials over a coefficient ring which is an arbitrary gcd domain.
++ The requirement on the coefficient domain guarantees that the \spadfun{content} can be
++ removed so that factors will be primitive as well as square-free.
++ Over an infinite ring of finite characteristic,it may not be possible to
++ guarantee that the factors are square-free.

    ++ \spad{op y = 0} must be one of the ai's in which case the equation for
    ++ \spad{z = y e^{-int ai}} is \spad{Li z = 0}.
    ++ \spad{ric} is a Riccati equation solver over \spad{F}, whose input
    ++ is the associated linear equation.
  polyRicDE: (L, UP -> List F) -> List POL
    ++ polyRicDE(op, zeros) returns
    ++ \spad{[[p1, L1], [p2, L2], ... , [pk, Lk]]} such that the polynomial
    ++ part of any rational solution of the associated Riccati equation of
    ++ \spad{op y=0} must be one of the pi's (up to the constant coefficient),
    ++ in which case the equation for \spad{z=y e^{-int p}} is \spad{Li z =0}.
    ++ \spad{zeros} is a zero finder in \spad{UP}.
  singRicDE: (L, (UP, UP2) -> List UP, UP -> Factored UP) -> List FRC
    ++ singRicDE(op, zeros, ezfactor) returns
    ++ \spad{[[f1, L1], [f2, L2], ... , [fk, Lk]]} such that the singular
    ++ part of any rational solution of the associated Riccati equation of
    ++ \spad{op y=0} must be one of the fi's (up to the constant coefficient),
    ++ in which case the equation for \spad{z=y e^{-int p}} is \spad{Li z=0}.
    ++ \spad{zeros(C(x),H(x,y))} returns all the \spad{P_i(x)}'s such that
    ++ \spad{H(x,P_i(x)) = 0 modulo C(x)}.
    ++ Argument \spad{ezfactor} is a factorisation in \spad{UP},
    ++ not necessarily into irreducibles.
  changeVar: (L, UP) -> L
    ++ changeVar(+/[ai D^i], a) returns the operator \spad{+/[ai (D+a)^i]}.
  changeVar: (L, RF) -> L
    ++ changeVar(+/[ai D^i], a) returns the operator \spad{+/[ai (D+a)^i]}.

17.125 package PRS PseudoRemainderSequence

The package constructor **PseudoRemainderSequence** provides efficient algorithms by Lionel Ducos (University of Poitiers, France) for computing subresultants. This leads to a speed up in many places in Axiom where subresultants are computed (polynomial system solving, algebraic factorization, integration).

17.126 PseudoRemainderSequence

)abbrev package INTPAF PureAlgebraicIntegration
++ Integration of pure algebraic functions;
++ Author: Manuel Bronstein
++ Date Created: 27 May 1988
++ Date Last Updated: 24 June 1994
++ Description:
++ This package provides functions for integration, limited integration,
++ extended integration and the risch differential equation for
++ pure algebraic integrands;
PureAlgebraicIntegration(R, F, L): Exports == Implementation where
  R: Join(GcdDomain,RetractableTo Integer,OrderedSet, CharacteristicZero,
          LinearlyExplicitRingOver Integer)
  F: Join(FunctionSpace R, AlgebraicallyClosedField,
          TranscendentalFunctionCategory)
  L: SetCategory

U3  ==> Union(Record(mainpart:F, limitedlogs:List LOG), "failed")
FAIL==> error "failed - cannot handle that integrand"

Exports ==> with
  palgint   : (F, K, K)    -> IR
    ++ palgint(f, x, y) returns the integral of \spad{f(x,y)dx}
    ++ where y is an algebraic function of x.
  palgextint: (F, K, K, F) -> U2
    ++ palgextint(f, x, y, g) returns functions \spad{[h, c]} such that
    ++ \spad{dh/dx = f(x,y) - c g}, where y is an algebraic function of x;
    ++ returns "failed" if no such functions exist.
  palglimint: (F, K, K, List F) -> U3
    ++ palglimint(f, x, y, [u1,...,un]) returns functions
    ++ \spad{[h,[[ci, ui]]]} such that the ui's are among \spad{[u1,...,un]}
    ++ and \spad{d(h + sum(ci log(ui)))/dx = f(x,y)} if such functions exist,
    ++ "failed" otherwise;
    ++ y is an algebraic function of x.
  palgRDE   : (F, F, F, K, K, (F, F, SY) -> U1) -> U1
    ++ palgRDE(nfp, f, g, x, y, foo) returns a function \spad{z(x,y)}
    ++ such that \spad{dz/dx + n * df/dx z(x,y) = g(x,y)} if such a z exists,
    ++ "failed" otherwise;
    ++ y is an algebraic function of x;
    ++ \spad{foo(a, b, x)} is a function that solves
    ++ \spad{du/dx + n * da/dx u(x) = u(x)}
    ++ for an unknown \spad{u(x)} not involving y.
    ++ \spad{nfp} is \spad{n * df/dx}.
  if L has LinearOrdinaryDifferentialOperatorCategory F then
    palgLODE: (L, F, K, K, SY) -> REC
      ++ palgLODE(op, g, kx, y, x) returns the solution of \spad{op f = g}.
      ++ y is an algebraic function of x.

```

```
++            J. Sym. Comp., April, 1992
++ Description:
++ \spadtype{QuasiAlgebraicSet2} adds a function \spadfun{radicalSimplify}
++ which uses \spadtype{IdealDecompositionPackage} to simplify
++ the representation of a quasi-algebraic set.  A quasi-algebraic set
++ is the intersection of a Zariski
++ closed set, defined as the common zeros of a given list of
++ polynomials (the defining polynomials for equations), and a principal
++ Zariski open set, defined as the complement of the common
++ zeros of a polynomial f (the defining polynomial for the inequation).
++ Quasi-algebraic sets are implemented in the domain
++ \spadtype{QuasiAlgebraicSet}, where two simplification routines are
++ provided:
++ \spadfun{idealSimplify} and \spadfun{simplify}.
++ The function
++ \spadfun{radicalSimplify} is added
++ for comparison study only.  Because the domain
++ \spadtype{IdealDecompositionPackage} provides facilities for
++ computing with radical ideals, it is necessary to restrict
++ the ground ring to the domain \spadtype{Fraction Integer},
++ and the polynomial ring to be of type
++ \spadtype{DistributedMultivariatePolynomial}.
++ The routine \spadfun{radicalSimplify} uses these to compute groebner
++ basis of radical ideals and
++ is inefficient and restricted when compared to the
++ two in \spadtype{QuasiAlgebraicSet}.

++ Factorization of extended polynomials with rational coefficients.
++ This package implements factorization of extended polynomials
++ whose coefficients are rational numbers. It does this by taking the
++ lcm of the coefficients of the polynomial and creating a polynomial
++ with integer coefficients. The algorithm in \spadtype{GaloisGroupFactorizer} i
++ used to factor the integer polynomial. The result is normalized
++ with respect to the original lcm of the denominators.

19.35 package RINTERP RationalInterpolation

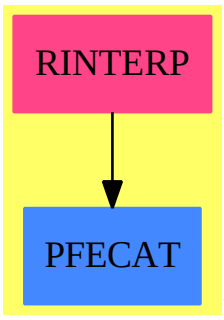
19.35.1 Introduction

This file contains a crude naïve implementation of rational interpolation, where the coefficients of the rational function are in any given field.

19.35.2 Questions and Outlook

- Maybe this file should be joined with pinterp.spad, where polynomial Lagrange interpolation is implemented. I have a second version that parallels the structure of pinterp.spad closely.
- There are probably better ways to implement rational interpolation. Maybe http://www.cs.ucsb.edu/ omer/personal/abstracts/rational.html contains something useful, but I don't know.
- Comments welcome!

19.36 RationalInterpolation



1.00

Exports:
interpolate

⟨*package RINTERP RationalInterpolation*⟩≡
```
)abbrev package RINTERP RationalInterpolation
++ Description:
++ This package exports rational interpolation algorithms
RationalInterpolation(xx,F): Exports == Implementation  where
    xx: Symbol
    F: Field
    Exports == with
        interpolate: (List F, List F, NonNegativeInteger,
                                  NonNegativeInteger) -> Fraction Polynomial F
```

The implementation sets up a system of linear equations and solves it.

⟨*package RINTERP RationalInterpolation*⟩+≡

```
Implementation == add
    interpolate(xlist, ylist, m, k) ==
```

First we check whether we have the right number of points and values. Clearly the number of points and the number of values must be identical. Note that we want to determine the numerator and denominator polynomials only up to a factor. Thus, we want to determine $m + k + 1$ coefficients, where m is the degree of the polynomial in the numerator and k is the degree of the polynomial in the denominator.

In fact, we could also leave – for example – k unspecified and determine it as $k = \#\texttt{xlist} - m - 1$: I don't know whether this would be better.

⟨*package RINTERP RationalInterpolation*⟩+≡

```
#xlist ^= #ylist =>
    error "Different number of points and values."
#xlist ^= m+k+1 =>
    error "wrong number of points"
```

The next step is to set up the matrix. Suppose that our numerator polynomial is $p(x) = a_0 + a_1 x + \ldots + a_m x^m$ and that our denominator polynomial is $q(x) = b_0 + b_1 x + \ldots + b_m x^m$. Then we have the following equations, writing n for $m + k + 1$:

$$\begin{aligned}
p(x_1) - y_1 q(x_1) &= a_0 + a_1 x_1 + \ldots + a_m x_1^m - y_1(b_0 + b_1 x_1 + \ldots + b_k x_1^k) = 0 \\
p(x_2) - y_2 q(x_2) &= a_0 + a_1 x_2 + \ldots + a_m x_2^m - y_2(b_0 + b_1 x_2 + \ldots + b_k x_2^k) = 0 \\
&\vdots \\
p(x_n) - y_n q(x_n) &= a_0 + a_1 x_n + \ldots + a_m x_n^m - y_n(b_0 + b_1 x_n + \ldots + b_k x_n^k) = 0
\end{aligned}$$

This can be written as

$$\begin{bmatrix}
1 & x_1 & \ldots & x_1^m & -y_1 & -y_1 x_1 & \ldots & -y_1 x_1^k \\
1 & x_2 & \ldots & x_2^m & -y_2 & -y_2 x_2 & \ldots & -y_2 x_2^k \\
 & & & \vdots & & & & \\
1 & x_n & \ldots & x_n^m & -y_n & -y_n x_n & \ldots & -y_n x_2^k
\end{bmatrix}
\begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_m \\ b_0 \\ b_1 \\ \vdots \\ b_k \end{bmatrix} = \mathbf{0}$$

We generate this matrix columnwise:

⟨*package RINTERP RationalInterpolation*⟩+≡

```
tempvec: List F := [1 for i in 1..(m+k+1)]

collist: List List F := cons(tempvec,
                             [(tempvec := [tempvec.i * xlist.i _
                                           for i in 1..(m+k+1)]) _
                              for j in 1..max(m,k)])

collist := append([collist.j for j in 1..(m+1)], _
                  [[- collist.j.i * ylist.i for i in 1..(m+k+1)] _
                   for j in 1..(k+1)])
```

Now we can solve the system:

⟨*package RINTERP RationalInterpolation*⟩+≡

```
res: List Vector F := nullSpace((transpose matrix collist) _
                                ::Matrix F)
```

Note that it may happen that the system has several solutions. In this case, some of the data points may not be interpolated correctly. However, the solution is often still useful, thus we do not signal an error.

⟨*package RINTERP RationalInterpolation*⟩+≡

```
if #res~=1 then output("Warning: unattainable points!" _
                       ::OutputForm)$OutputPackage
```

In this situation, all the solutions will be equivalent, thus we can always simply take the first one:

⟨*package RINTERP RationalInterpolation*⟩+≡

```
reslist: List List Polynomial F := _
          [[(res.1).(i+1)*(xx::Polynomial F)**i for i in 0..m], _
          [(res.1).(i+m+2)*(xx::Polynomial F)**i for i in 0..k]]
```

Finally, we generate the rational function:

⟨*package RINTERP RationalInterpolation*⟩+≡

```
reduce((_+),reslist.1)/reduce((_+),reslist.2)
```

⟨*RINTERP.dotabb*⟩≡

```
"RINTERP" [color="#FF4488",href="bookvol10.4.pdf#nameddest=RINTERP"]
"PFECAT" [color="#4488FF",href="bookvol10.2.pdf#nameddest=PFECAT"]
"RINTERP" -> "PFECAT"
```

++ AMS Classifications:
++ Description:
++   A package for computing the rational univariate representation
++   of a zero-dimensional algebraic variety given by a regular
++   triangular set. This package is essentially an interface for the
++  \spadtype{InternalRationalUnivariateRepresentationPackage} constructor.
++  It is used in the \spadtype{ZeroDimensionalSolvePackage}
++  for solving polynomial systems with finitely many solutions.
++ Version: 1.

RationalUnivariateRepresentationPackage(R,ls): Exports == Implementation where
  R : Join(EuclideanDomain,CharacteristicZero)
  ls: List Symbol
  N ==> NonNegativeInteger
  Z ==> Integer
  P ==> Polynomial R
  LP ==> List P
  U ==> SparseUnivariatePolynomial(R)
  RUR ==> Record(complexRoots: U, coordinates: LP)
```

```
Exports ==  with

   rur: (LP,Boolean) -> List RUR
     ++ \spad{rur(lp,univ?)} returns a rational univariate representation
     ++ of \spad{lp}. This assumes that \spad{lp} defines a regular
     ++ triangular \spad{ts} whose associated variety is zero-dimensional
     ++ over \spad{R}. \spad{rur(lp,univ?)} returns a list of items
     ++ \spad{[u,lc]} where \spad{u} is an irreducible univariate polynomial
     ++ and each \spad{c} in \spad{lc} involves two variables: one from \spad{ls},
     ++ called the coordinate of \spad{c}, and an extra variable which
     ++ represents any root of \spad{u}. Every root of \spad{u} leads to
     ++ a tuple of values for the coordinates of \spad{lc}. Moreover,
     ++ a point \spad{x} belongs to the variety associated with \spad{lp} iff
     ++ there exists an item \spad{[u,lc]} in \spad{rur(lp,univ?)} and
     ++ a root \spad{r} of \spad{u} such that \spad{x} is given by the
     ++ tuple of values for the coordinates of \spad{lc} evaluated at \spad{r}.
     ++ If \spad{univ?} is \spad{true} then each polynomial \spad{c}
     ++ will have a constant leading coefficient w.r.t. its coordinate.
     ++ See the example which illustrates the \spadtype{ZeroDimensionalSolvePackage}
     ++ package constructor.
   rur: (LP) -> List RUR
     ++ \spad{rur(lp)} returns the same as \spad{rur(lp,true)}
   rur: (LP,Boolean,Boolean) -> List RUR
     ++ \spad{rur(lp,univ?,check?)} returns the same as \spad{rur(lp,true)}.
     ++ Moreover, if \spad{check?} is \spad{true} then the result is checked.

19.45 package POLUTIL RealPolynomialUtilitiesPackage

This file describes the Real Closure 1.0 package which consists of different packages, categoris and domains :

The package RealPolynomialUtilitiesPackage whichs receives a field and a univariate polynomial domain with coefficients in the field. It computes some simple functions such as Strum and Sylvester sequences.

The category RealRootCharacterizationCategory provides abstarct functionalities to work with "real roots" of univariate polynomials. These resemble variables with some functionalities needed to compute important operations.

RealClosedField is a category with provides common operations available over real closed fiels. These include finding all the roots of univariate polynomial, taking square roots, ...

CAVEATS

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every cretaion function raises a new "real root". This has the effect that when you type something like sqrt(2) + sqrt(2) you have two new variables which happen to be equal. To avoid this name the expression such as in s2 := sqrt(2) ; s2 + s2

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which most natural to you.

LIMITATIONS

The file reclos.input show some basic use of the package. This packages uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Betas versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done excatly. They can thus be quite time consuming when depending on several “real roots”.

  Implementation == add
```

⟨*implementation: RecurrenceOperator*⟩

19.56.1 Defining new operators

We define two new operators, one for recurrences, the other for functional equations. The operators for recurrences represents the n^{th} term of the corresponding sequence, the other the coefficient of x^n in the Taylor series expansion.

⟨*implementation: RecurrenceOperator*⟩≡

```
    oprecur := operator("rootOfRec"::Symbol)$BasicOperator

    opADE := operator("rootOfADE"::Symbol)$BasicOperator

    setProperty(oprecur, "%dummyVar", 2 pretend None)
    setProperty(opADE, "%dummyVar", 2 pretend None)
```

Setting these properties implies that the second and third arguments of oprecur are dummy variables and affects `tower$ES`: the second argument will not appear in `tower$ES`, if it does not appear in any argument but the first and second. The third argument will not appear in `tower$ES`, if it does not appear in any other argument. (`%defsum` is a good example)

The arguments of the two operators are as follows:

1. `eq`, i.e. the vanishing expression

   ⟨*implementation: RecurrenceOperator*⟩+≡
   ```
   eqAsF: List F -> F
   eqAsF l == l.1
   ```

2. `dummy`, a dummy variable to make substitutions possible

   ⟨*implementation: RecurrenceOperator*⟩+≡
   ```
   dummy: List F -> Symbol
   dummy l == retract(l.2)@Symbol

   dummyAsF: List F -> F
   dummyAsF l == l.2
   ```

3. the variable for display

   ⟨*implementation: RecurrenceOperator*⟩+≡
   ```
   displayVariable: List F -> F
   displayVariable l == l.3
   ```

4. `operatorName(argument)`

   ⟨*implementation: RecurrenceOperator*⟩+≡
   ```
   operatorName: List F -> BasicOperator
   operatorName l == operator(kernels(l.4).1)

   operatorNameAsF: List F -> F
   operatorNameAsF l == l.4

   operatorArgument: List F -> F
   operatorArgument l == argument(kernels(l.4).1).1
   ```

Concerning `rootOfADE`, note that although we have `arg` as argument of the operator, it is intended to indicate the coefficient, not the argument of the power series.

5. `values` in reversed order.

   - `rootOfRec`: maybe `values` should be preceded by the index of the first given value. Currently, the last value is interpreted as $f(0)$.
   - `rootOfADE`: values are the first few coefficients of the power series expansion in order.

⟨*implementation: RecurrenceOperator*⟩+≡

```
initialValues: List F -> List F
initialValues l == rest(l, 4)
```

19.56.2 Recurrences

Extracting some information from the recurrence

We need to find out wether we can determine the next term of the sequence, and how many initial values are necessary.

⟨*implementation: RecurrenceOperator*⟩+≡

```
      if R has Ring then
        getShiftRec(op: BasicOperator, f: Kernel F, n: Symbol)
                    : Union(Integer, "failed") ==
            a := argument f
            if every?(freeOf?(#1, n::F), a) then return 0

            if #a ~= 1 then error "RECOP: operator should have only one argument"

            p := univariate(a.1, retract(n::F)@Kernel(F))
            if denominator p ~= 1 then return "failed"

            num := numer p

            if degree num = 1 and coefficient(num, 1) = 1
               and every?(freeOf?(#1, n::F), coefficients num)
            then return retractIfCan(coefficient(num, 0))
            else return "failed"

  -- if the recurrence is of the form
  -- $p(n, f(n+m-o), f(n+m-o+1), \dots, f(n+m)) = 0$
  -- in which case shiftInfoRec returns [m, o, f(n+m)].

        shiftInfoRec(op: BasicOperator, argsym: Symbol, eq: F):
                     Record(max: Union(Integer, "failed"),
                            ord: Union(Integer, "failed"),
                            ker: Kernel F) ==

  -- ord and ker are valid only if all shifts are Integers
  -- ker is the kernel of the maximal shift.
          maxShift: Integer
          minShift: Integer
          nextKernel: Kernel F

  -- We consider only those kernels that have op as operator. If there is none,
  -- we raise an error. For the moment we don't allow recursions that contain op
  -- inside of another operator.

          error? := true
```

```
for f in kernels eq repeat
  if is?(f, op) then
    shift := getShiftRec(op, f, argsym)
    if error? then
      error? := false
      nextKernel := f
      if shift case Integer then
        maxShift := shift
        minShift := shift
      else return ["failed", "failed", nextKernel]
    else
      if shift case Integer then
        if maxShift < shift then
          maxShift := shift
          nextKernel := f
        if minShift > shift then
          minShift := shift
      else return ["failed", "failed", nextKernel]

if error? then error "evalRec: equation does not contain operator"

[maxShift, maxShift - minShift, nextKernel]
```

Evaluating a recurrence

⟨*implementation: RecurrenceOperator*⟩+≡

```
        evalRec(op, argsym, argdisp, arg, eq, values) ==
          if ((n := retractIfCan(arg)@Union(Integer, "failed")) case "failed")
             or (n < 0)
          then
            shiftInfo := shiftInfoRec(op, argsym, eq)

            if (shiftInfo.ord case "failed") or ((shiftInfo.ord)::Integer > 0)
            then
              kernel(oprecur,
                     append([eq, argsym::F, argdisp, op(arg)], values))
            else
              p := univariate(eq, shiftInfo.ker)
              num := numer p

  -- If the degree is 1, we can return the function explicitly.

              if degree num = 1 then
                eval(-coefficient(num, 0)/coefficient(num, 1), argsym::F,
                     arg::F-(shiftInfo.max)::Integer::F)
              else
                kernel(oprecur,
                       append([eq, argsym::F, argdisp, op(arg)], values))
          else
            len: Integer := #values
            if n < len
            then values.(len-n)
            else
              shiftInfo := shiftInfoRec(op, argsym, eq)

              if shiftInfo.max case Integer then
                p := univariate(eq, shiftInfo.ker)

                num := numer p

                if degree num = 1 then

                  next := -coefficient(num, 0)/coefficient(num, 1)
                  nextval := eval(next, argsym::F,
                                  (len-(shiftInfo.max)::Integer)::F)
                  newval := eval(nextval, op,
                                 evalRec(op, argsym, argdisp, #1, eq, values))
                  evalRec(op, argsym, argdisp, arg, eq, cons(newval, values))
                else
```

```
            kernel(oprecur,
                   append([eq, argsym::F, argdisp, op(arg)], values))

          else
            kernel(oprecur,
                   append([eq, argsym::F, argdisp, op(arg)], values))

      numberOfValuesNeeded(numberOfValues: Integer,
                           op: BasicOperator, argsym: Symbol, eq: F): Integer ==
        order := shiftInfoRec(op, argsym, eq).ord
        if order case Integer
        then min(numberOfValues, retract(order)@Integer)
        else numberOfValues

    else
      evalRec(op, argsym, argdisp, arg, eq, values) ==
        kernel(oprecur,
               append([eq, argsym::F, argdisp, op(arg)], values))

                           op: BasicOperator, argsym: Symbol, eq: F): Integer ==
        numberOfValues
```

Setting the evaluation property of `oprecur`

`irecur` is just a wrapper that allows us to write a recurrence relation as an operator.

⟨*implementation: RecurrenceOperator*⟩+≡

```
    irecur: List F -> F
    irecur l ==
      evalRec(operatorName l,
              dummy l, displayVariable l,
              operatorArgument l, eqAsF l, initialValues l)

    evaluate(oprecur, irecur)$BasicOperatorFunctions1(F)
```

Displaying a recurrence relation

⟨*implementation: RecurrenceOperator*⟩+≡

```
ddrec: List F -> OutputForm
ddrec l ==
  op := operatorName l
  values := reverse l
  eq := eqAsF l

  numberOfValues := numberOfValuesNeeded(#values-4, op, dummy l, eq)

  vals: List OutputForm
       := cons(eval(eq, dummyAsF l, displayVariable l)::OutputForm = _
               0::OutputForm,
               [elt(op::OutputForm, [(i-1)::OutputForm]) = _
                (values.i)::OutputForm
                for i in 1..numberOfValues])

  bracket(hconcat([(operatorNameAsF l)::OutputForm,
                   ": ",
                   commaSeparate vals]))

setProperty(oprecur, "%specialDisp",
            ddrec@(List F -> OutputForm) pretend None)
```

19.56.3 Functional Equations

Determining the number of initial values for ADE's

We use Joris van der Hoeven's instructions for ADE's. Given $Q = p(f, f', \ldots, f^{(r)})$ we first need to differentiate Q with respect to $f^{(i)}$ for $i \in \{0, 1, \ldots, r\}$, plug in the given truncated power series solution and determine the valuation.

⟨*NOTYET implementation: RecurrenceOperator*⟩≡

```
getValuation(op, argsym, eq, maxorder, values): Integer ==
    max: Integer := -1;
    ker: Kernel F
    for i in 0..maxorder repeat
        ker := D(op(argsym), argsym, i)::Kernel F
        pol := univariate(eq, ker)
        dif := D pol
        ground numer(dif.D(op(argsym), argsym, i))
```

Extracting some information from the functional equation

`getOrder` returns the maximum derivative of `op` occurring in `f`.

⟨*implementation: RecurrenceOperator*⟩+≡

```
getOrder(op: BasicOperator, f: Kernel F): NonNegativeInteger ==
  res: NonNegativeInteger := 0
  g := f
  while is?(g, %diff) repeat
    g := kernels(argument(g).1).1
    res := res+1

  if is?(g, op) then res else 0
```

⟨*package RSDCMPK RegularSetDecompositionPackage*⟩≡

```
)abbrev package RSDCMPK RegularSetDecompositionPackage
++ Author: Marc Moreno Maza
++ Date Created: 09/16/1998
++ Date Last Updated: 12/16/1998
++ Basic Functions:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ Description:
++ A package providing a new algorithm for solving polynomial systems
++ by means of regular chains. Two ways of solving are proposed:
++ in the sense of Zariski closure (like in Kalkbrener's algorithm)
++ or in the sense of the regular zeros (like in Wu, Wang or Lazard
++ methods). This algorithm is valid for nay type
++ of regular set. It does not care about the way a polynomial is
++ added in an regular set, or how two quasi-components are compared
++ (by an inclusion-test), or how the invertibility test is made in
++ the tower of simple extensions associated with a regular set.
++ These operations are realized respectively by the domain \spad{TS}
++ and the packages
++ \axiomType{QCMPACK}(R,E,V,P,TS) and \axiomType{RSETGCD}(R,E,V,P,TS).
++ The same way it does not care about the way univariate polynomial
++ gcd (with coefficients in the tower of simple extensions associated
```

```
++ with a regular set) are computed. The only requirement is that these
++ gcd need to have invertible initials (normalized or not).
++ WARNING. There is no need for a user to call diectly any operation
++ of this package since they can be accessed by the domain \axiom{TS}.
++ Thus, the operations of this package are not documented.\newline
++ References :
++  [1] M. MORENO MAZA "A new algorithm for computing triangular
++      decomposition of algebraic varieties" NAG Tech. Rep. 4/98.
++ Version: 5. Same as 4 but Does NOT use any unproved criteria.

++ Description:
++   RepresentationPackage1 provides functions for representation theory
++   for finite groups and algebras.
++   The package creates permutation representations and uses tensor products
++   and its symmetric and antisymmetric components to create new
++   representations of larger degree from given ones.
```

```
++   Note: instead of having parameters from \spadtype{Permutation}
++   this package allows list notation of permutations as well:
++   e.g. \spad{[1,4,3,2]} denotes permutes 2 and 4 and fixes 1 and 3.

++ Description:
++   RepresentationPackage2 provides functions for working with
++   modular representations of finite groups and algebra.
++   The routines in this package are created, using ideas of R. Parker,
++   (the meat-Axe) to get smaller representations from bigger ones,
++   i.e. finding sub- and factormodules, or to show, that such the
```

```
++   representations are irreducible.
++   Note: most functions are randomized functions of Las Vegas type
++   i.e. every answer is correct, but with small probability
++   the algorithm fails to get an answer.

  public ==> with

    completeEchelonBasis : V V R  ->  M R
      ++ completeEchelonBasis(lv) completes the basis {\em lv} assumed
      ++ to be in echelon form of a subspace of {\em R**n} (n the length
      ++ of all the vectors in {\em lv}) with unit vectors to a basis of
      ++ {\em R**n}. It is assumed that the argument is not an empty
      ++ vector and that it is not the basis of the 0-subspace.
      ++ Note: the rows of the result correspond to the vectors of the basis.
    createRandomElement : (L M R, M R) -> M R
      ++ createRandomElement(aG,x) creates a random element of the group
      ++ algebra generated by {\em aG}.
    -- randomWord : (L L I, L M)  ->  M R
      --++ You can create your own 'random' matrix with "randomWord(lli, lm)".
      --++ Each li in lli determines a product of matrices, the entries in li
      --++ determine which matrix from lm is chosen. Finally we sum over all
      --++ products. The result "sm" can be used to call split with (e.g.)
      --++ second parameter "first nullSpace sm"
    if R has EuclideanDomain then   -- using rowEchelon
      cyclicSubmodule  : (L M R, V R) ->   V V R
        ++ cyclicSubmodule(lm,v) generates a basis as follows.
        ++ It is assumed that the size n of the vector equals the number
        ++ of rows and columns of the matrices. Then the matrices generate
        ++ a subalgebra, say \spad{A}, of the algebra of all square matrices of
        ++ dimension n. {\em V R} is an \spad{A}-module in the natural way.
        ++ cyclicSubmodule(lm,v) generates the R-Basis of {\em Av} as
        ++ described in section 6 of R. A. Parker's "The Meat-Axe".
        ++ Note: in contrast to the description in "The Meat-Axe" and to
```

```
      ++ {\em standardBasisOfCyclicSubmodule} the result is in
      ++ echelon form.
    standardBasisOfCyclicSubmodule  : (L M R, V R) ->   M R
      ++ standardBasisOfCyclicSubmodule(lm,v) returns a matrix as follows.
      ++ It is assumed that the size n of the vector equals the number
      ++ of rows and columns of the matrices.  Then the matrices generate
      ++ a subalgebra, say \spad{A},
      ++ of the algebra of all square matrices of
      ++ dimension n. {\em V R} is an \spad{A}-module in the natural way.
      ++ standardBasisOfCyclicSubmodule(lm,v) calculates a matrix whose
      ++ non-zero column vectors are the R-Basis of {\em Av} achieved
      ++ in the way as described in section 6
      ++ of R. A. Parker's "The Meat-Axe".
      ++ Note: in contrast to {\em cyclicSubmodule}, the result is not
      ++ in echelon form.
  if R has Field then  -- only because of inverse in SM
    areEquivalent? : (L M R, L M R, B, I) -> M R
      ++ areEquivalent?(aG0,aG1,randomelements,numberOfTries) tests
      ++ whether the two lists of matrices, all assumed of same
      ++ square shape, can be simultaneously conjugated by a non-singular
      ++ matrix. If these matrices represent the same group generators,
      ++ the representations are equivalent.
      ++ The algorithm tries
      ++ {\em numberOfTries} times to create elements in the
      ++ generated algebras in the same fashion. If their ranks differ,
      ++ they are not equivalent. If an
      ++ isomorphism is assumed, then
      ++ the kernel of an element of the first algebra
      ++ is mapped to the kernel of the corresponding element in the
      ++ second algebra. Now consider the one-dimensional ones.
      ++ If they generate the whole space (e.g. irreducibility !)
      ++ we use {\em standardBasisOfCyclicSubmodule} to create the
      ++ only possible transition matrix. The method checks whether the
      ++ matrix conjugates all corresponding matrices from {\em aGi}.
      ++ The way to choose the singular matrices is as in {\em meatAxe}.
      ++ If the two representations are equivalent, this routine
      ++ returns the transformation matrix {\em TM} with
      ++ {\em aG0.i * TM = TM * aG1.i} for all i. If the representations
      ++ are not equivalent, a small 0-matrix is returned.
      ++ Note: the case
      ++ with different sets of group generators cannot be handled.
    areEquivalent? : (L M R, L M R) -> M R
      ++ areEquivalent?(aG0,aG1) calls {\em areEquivalent?(aG0,aG1,true,25)}.
      ++ Note: the choice of 25 was rather arbitrary.
    areEquivalent? : (L M R, L M R, I) -> M R
      ++ areEquivalent?(aG0,aG1,numberOfTries) calls
```

```
      ++ {\em areEquivalent?(aG0,aG1,true,25)}.
      ++ Note: the choice of 25 was rather arbitrary.
    isAbsolutelyIrreducible? : (L M R, I) -> B
      ++ isAbsolutelyIrreducible?(aG, numberOfTries) uses
      ++ Norton's irreducibility test to check for absolute
      ++ irreduciblity, assuming if a one-dimensional kernel is found.
      ++ As no field extension changes create "new" elements
      ++ in a one-dimensional space, the criterium stays true
      ++ for every extension. The method looks for one-dimensionals only
      ++ by creating random elements (no fingerprints) since
      ++ a run of {\em meatAxe} would have proved absolute irreducibility
      ++ anyway.
    isAbsolutelyIrreducible? : L M R -> B
      ++ isAbsolutelyIrreducible?(aG) calls
      ++ {\em isAbsolutelyIrreducible?(aG,25)}.
      ++ Note: the choice of 25 was rather arbitrary.
    split : (L M R, V R)  ->  L L M R
      ++ split(aG, vector) returns a subalgebra \spad{A} of all
      ++ square matrix of dimension n as a list of list of matrices,
      ++ generated by the list of matrices aG, where n denotes both
      ++ the size of vector as well as the dimension of each of the
      ++ square matrices.
      ++ {\em V R} is an A-module in the natural way.
      ++ split(aG, vector) then checks whether the cyclic submodule
      ++ generated by {\em vector} is a proper submodule of {\em V R}.
      ++ If successful, it returns a two-element list, which contains
      ++ first the list of the representations of the submodule,
      ++ then the list of the representations of the factor module.
      ++ If the vector generates the whole module, a one-element list
      ++ of the old representation is given.
      ++ Note: a later version this should call the other split.
    split:  (L M R, V V R) -> L L M R
      ++ split(aG,submodule) uses a proper submodule of {\em R**n}
      ++ to create the representations of the submodule and of
      ++ the factor module.
  if (R has Finite) and (R has Field) then
    meatAxe  : (L M R, B, I, I)  ->  L L M R
      ++ meatAxe(aG,randomElements,numberOfTries, maxTests) returns
      ++ a 2-list of representations as follows.
      ++ All matrices of argument aG are assumed to be square
      ++ and of equal size.
      ++ Then \spad{aG} generates a subalgebra, say \spad{A}, of the algebra
      ++ of all square matrices of dimension n. {\em V R} is an A-module
      ++ in the usual way.
      ++ meatAxe(aG,numberOfTries, maxTests) creates at most
      ++ {\em numberOfTries} random elements of the algebra, tests
```

```
    ++ them for singularity. If singular, it tries at most {\em maxTests}
    ++ elements of its kernel to generate a proper submodule.
    ++ If successful, a 2-list is returned: first, a list
    ++ containing first the list of the
    ++ representations of the submodule, then a list of the
    ++ representations of the factor module.
    ++ Otherwise, if we know that all the kernel is already
    ++ scanned, Norton's irreducibility test can be used either
    ++ to prove irreducibility or to find the splitting.
    ++ If {\em randomElements} is {\em false}, the first 6 tries
    ++ use Parker's fingerprints.
  meatAxe : L M R -> L L M R
    ++ meatAxe(aG) calls {\em meatAxe(aG,false,25,7)} returns
    ++ a 2-list of representations as follows.
    ++ All matrices of argument \spad{aG} are assumed to be square
    ++ and of
    ++ equal size. Then \spad{aG} generates a subalgebra,
    ++ say \spad{A}, of the algebra
    ++ of all square matrices of dimension n. {\em V R} is an A-module
    ++ in the usual way.
    ++ meatAxe(aG) creates at most 25 random elements
    ++ of the algebra, tests
    ++ them for singularity. If singular, it tries at most 7
    ++ elements of its kernel to generate a proper submodule.
    ++ If successful a list which contains first the list of the
    ++ representations of the submodule, then a list of the
    ++ representations of the factor module is returned.
    ++ Otherwise, if we know that all the kernel is already
    ++ scanned, Norton's irreducibility test can be used either
    ++ to prove irreducibility or to find the splitting.
    ++ Notes: the first 6 tries use Parker's fingerprints.
    ++ Also, 7 covers the case of three-dimensional kernels over
    ++ the field with 2 elements.
  meatAxe: (L M R, B) ->  L L M R
    ++ meatAxe(aG, randomElements) calls {\em meatAxe(aG,false,6,7)},
    ++ only using Parker's fingerprints, if {\em randomElemnts} is false.
    ++ If it is true, it calls {\em  meatAxe(aG,true,25,7)},
    ++ only using random elements.
    ++ Note: the choice of 25 was rather arbitrary.
    ++ Also, 7 covers the case of three-dimensional kernels over the field
    ++ with 2 elements.
  meatAxe : (L M R, PI)  ->  L L M R
    ++ meatAxe(aG, numberOfTries) calls
    ++ {\em meatAxe(aG,true,numberOfTries,7)}.
    ++ Notes: 7 covers the case of three-dimensional
    ++ kernels over the field with 2 elements.
```

```
    scanOneDimSubspaces: (L V R, I)  ->  V R
      ++ scanOneDimSubspaces(basis,n) gives a canonical representative
      ++ of the {\em n}-th one-dimensional subspace of the vector space
      ++ generated by the elements of {\em basis}, all from {\em R**n}.
      ++ The coefficients of the representative are of shape
      ++ {\em (0,...,0,1,*,...,*)}, {\em *} in R. If the size of R
      ++ is q, then there are {\em (q**n-1)/(q-1)} of them.
      ++ We first reduce n modulo this number, then find the
      ++ largest i such that {\em +/[q**i for i in 0..i-1] <= n}.
      ++ Subtracting this sum of powers from n results in an
      ++ i-digit number to basis q. This fills the positions of the
      ++ stars.

++ Date Last Updated: May 30, 1991
++ Basic Operations:
++ Related Domains: ErrorFunctions, Exit, Void
++ Also See:
++ AMS Classifications:
++ Keywords: mode, resolve, type lattice
++ Examples:
++ References:
++ Description:
++   This package provides coercions for the special types \spadtype{Exit}
++   and \spadtype{Void}.
ResolveLatticeCompletion(S: Type): with
        coerce: S -> Void
             ++ coerce(s) throws all information about s away.
             ++ This coercion allows values of any type to appear
             ++ in contexts where they will not be used.
             ++ For example, it allows the resolution of different types in
             ++ the \spad{then} and \spad{else} branches when an \spad{if}
             ++ is in a context where the resulting value is not used.
        coerce: Exit -> S
             ++ coerce(e) is never really evaluated.  This coercion is
             ++ used for formal type correctness when a function will not
             ++ return directly to its caller.
```

++ Cache of elements in a set
++ Author: Manuel Bronstein
++ Date Created: 31 Oct 1988
++ Date Last Updated: 14 May 1991
++   A sorted cache of a cachable set S is a dynamic structure that
++   keeps the elements of S sorted and assigns an integer to each
++   element of S once it is in the cache. This way, equality and ordering
++   on S are tested directly on the integers associated with the elements
++   of S, once they have been entered in the cache.
SortedCache(S:CachableSet): Exports == Implementation where
  N    ==> NonNegativeInteger
  DIFF ==> 1024

  Exports ==> with
    clearCache  : () -> Void
      ++ clearCache() empties the cache.
    cache       : () -> List S
      ++ cache() returns the current cache as a list.
    enterInCache: (S, S -> Boolean) -> S
      ++ enterInCache(x, f) enters x in the cache, calling \spad{f(y)} to
      ++ determine whether x is equal to y. It returns x with an integer
      ++ associated with it.
    enterInCache: (S, (S, S) -> Integer) -> S
      ++ enterInCache(x, f) enters x in the cache, calling \spad{f(x, y)} to
      ++ determine whether \spad{x < y (f(x,y) < 0), x = y (f(x,y) = 0)}, or
      ++ \spad{x > y (f(x,y) > 0)}.
```

```

++ AMS Classifications:
++ Keywords:
++ Description:
++ A package providing a new algorithm for solving polynomial systems
++ by means of regular chains. Two ways of solving are provided:
++ in the sense of Zariski closure (like in Kalkbrener's algorithm)
++ or in the sense of the regular zeros (like in Wu, Wang or Lazard-
++ Moreno methods). This algorithm is valid for nay type
++ of regular set. It does not care about the way a polynomial is
++ added in an regular set, or how two quasi-components are compared
++ (by an inclusion-test), or how the invertibility test is made in
++ the tower of simple extensions associated with a regular set.
++ These operations are realized respectively by the domain \spad{TS}
++ and the packages \spad{QCMPPK(R,E,V,P,TS)} and \spad{RSETGCD(R,E,V,P,TS)}.
++ The same way it does not care about the way univariate polynomial
++ gcds (with coefficients in the tower of simple extensions associated
++ with a regular set) are computed. The only requirement is that these
```

```
++ gcds need to have invertible initials (normalized or not).
++ WARNING. There is no need for a user to call diectly any operation
++ of this package since they can be accessed by the domain \axiomType{TS}.
++ Thus, the operations of this package are not documented.\newline

++ Description:
++ A internal package for computing gcds and resultants of univariate polynomials
++ with coefficients in a tower of simple extensions of a field.
++ There is no need to use directly this package since its main operations are
++ available from \spad{TS}. \newline
++ References :

++ Description:
++   This package provides standard arithmetic operations on matrices.
++   The functions in this package store the results of computations
++   in existing matrices, rather than creating new matrices.  This
++   package works only for matrices of type Matrix and uses the
++   internal representation of this type.

20.39 package STTAYLOR StreamTaylorSeriesOperations

Problems raising a UTS to a negative integer power.

The code in `powern(rn,x)` which raises an unnecessary error where no distinction between rational and integer powers are made.

The fix is easy. Since the problem does not exist in SUPS we can just take the definition there.

    "+"          : (ST A,ST A) -> ST A
      ++ a + b returns the power series sum of \spad{a} and \spad{b}:
      ++ \spad{[a0,a1,..] + [b0,b1,..] = [a0 + b0,a1 + b1,..]}
    "-"          : (ST A,ST A) -> ST A
      ++ a - b returns the power series difference of \spad{a} and
      ++ \spad{b}: \spad{[a0,a1,..] - [b0,b1,..] = [a0 - b0,a1 - b1,..]}
    "-"          : ST A -> ST A
      ++ - a returns the power series negative of \spad{a}:
      ++ \spad{- [a0,a1,...] = [- a0,- a1,...]}
    "*"          : (ST A,ST A) -> ST A
      ++ a * b returns the power series (Cauchy) product of \spad{a} and b:
      ++ \spad{[a0,a1,...] * [b0,b1,...] = [c0,c1,...]} where
      ++ \spad{ck = sum(i + j = k,ai * bk)}.
    "*"          : (A,ST A) -> ST A
      ++ r * a returns the power series scalar multiplication of r by \spad{a}:
      ++ \spad{r * [a0,a1,...] = [r * a0,r * a1,...]}
    "*"          : (ST A,A) -> ST A
      ++ a * r returns the power series scalar multiplication of \spad{a} by r:
      ++ \spad{[a0,a1,...] * r = [a0 * r,a1 * r,...]}
    "exquo"      : (ST A,ST A) -> Union(ST A,"failed")
      ++ exquo(a,b) returns the power series quotient of \spad{a} by b,
      ++ if the quotient exists, and "failed" otherwise
    "/"          : (ST A,ST A) -> ST A
      ++ a / b returns the power series quotient of \spad{a} by b.
      ++ An error message is returned if \spad{b} is not invertible.
      ++ This function is used in fixed point computations.
    recip        : ST A -> UN
      ++ recip(a) returns the power series reciprocal of \spad{a}, or
      ++ "failed" if not possible.
```

```
monom        : (A,I) -> ST A
  ++ monom(deg,coef) is a monomial of degree deg with coefficient
  ++ coef.
integers     : I -> ST I
  ++ integers(n) returns \spad{[n,n+1,n+2,...]}.
oddintegers  : I -> ST I
  ++ oddintegers(n) returns \spad{[n,n+2,n+4,...]}.
int          : A -> ST A
  ++ int(r) returns [r,r+1,r+2,...], where r is a ring element.
mapmult      : (ST A,ST A) -> ST A
  ++ mapmult([a0,a1,..],[b0,b1,..])
  ++ returns \spad{[a0*b0,a1*b1,..]}.
deriv        : ST A -> ST A
  ++ deriv(a) returns the derivative of the power series with
  ++ respect to the power series variable. Thus
  ++ \spad{deriv([a0,a1,a2,...])} returns \spad{[a1,2 a2,3 a3,...]}.
gderiv       : (I -> A,ST A)  -> ST A
  ++ gderiv(f,[a0,a1,a2,..]) returns
  ++ \spad{[f(0)*a0,f(1)*a1,f(2)*a2,..]}.
coerce       : A -> ST A
  ++ coerce(r) converts a ring element r to a stream with one element.
eval         : (ST A,A) -> ST A
  ++ eval(a,r) returns a stream of partial sums of the power series
  ++ \spad{a} evaluated at the power series variable equal to r.
compose      : (ST A,ST A) -> ST A
  ++ compose(a,b) composes the power series \spad{a} with
  ++ the power series b.
lagrange     : ST A -> ST A
  ++ lagrange(g) produces the power series for f where f is
  ++ implicitly defined as \spad{f(z) = z*g(f(z))}.
revert       : ST A -> ST A
  ++ revert(a) computes the inverse of a power series \spad{a}
  ++ with respect to composition.
  ++ the series should have constant coefficient 0 and first
  ++ order coefficient 1.
addiag       : ST ST A -> ST A
  ++ addiag(x) performs diagonal addition of a stream of streams. if x =
  ++ \spad{[[a<0,0>,a<0,1>,..],[a<1,0>,a<1,1>,..],[a<2,0>,a<2,1>,..],..]}
  ++ and \spad{addiag(x) = [b<0,b<1>,...], then b<k> = sum(i+j=k,a<i,j>)}.
lambert      : ST A -> ST A
  ++ lambert(st) computes \spad{f(x) + f(x**2) + f(x**3) + ...}
  ++ if st is a stream representing \spad{f(x)}.
  ++ This function is used for computing infinite products.
  ++ If \spad{f(x)} is a power series with constant coefficient 1 then
  ++ \spad{prod(f(x**n),n = 1..infinity) = exp(lambert(log(f(x))))}.
oddlambert   : ST A -> ST A
```

```
    ++ oddlambert(st) computes \spad{f(x) + f(x**3) + f(x**5) + ...}
    ++ if st is a stream representing \spad{f(x)}.
    ++ This function is used for computing infinite products.
    ++ If f(x) is a power series with constant coefficient 1 then
    ++ \spad{prod(f(x**(2*n-1)),n=1..infinity) = exp(oddlambert(log(f(x))))}.
  evenlambert  : ST A -> ST A
    ++ evenlambert(st) computes \spad{f(x**2) + f(x**4) + f(x**6) + ...}
    ++ if st is a stream representing \spad{f(x)}.
    ++ This function is used for computing infinite products.
    ++ If \spad{f(x)} is a power series with constant coefficient 1, then
    ++ \spad{prod(f(x**(2*n)),n=1..infinity) = exp(evenlambert(log(f(x))))}.
  generalLambert : (ST A,I,I) -> ST A
    ++ generalLambert(f(x),a,d) returns
    ++ \spad{f(x**a) + f(x**(a + d)) + f(x**(a + 2 d)) + ...}.
    ++ \spad{f(x)} should have zero constant
    ++ coefficient and \spad{a} and d should be positive.
  multisect    : (I,I,ST A) -> ST A
    ++ multisect(a,b,st)
    ++ selects the coefficients of \spad{x**((a+b)*n+a)},
    ++ and changes them to \spad{x**n}.
  invmultisect : (I,I,ST A) -> ST A
    ++ invmultisect(a,b,st) substitutes \spad{x**((a+b)*n)} for \spad{x**n}
    ++ and multiplies by \spad{x**b}.
  if A has Algebra RN then
    integrate  : (A,ST A) -> ST A
      ++ integrate(r,a) returns the integral of the power series \spad{a}
      ++ with respect to the power series variableintegration where
      ++ r denotes the constant of integration. Thus
      ++ \spad{integrate(a,[a0,a1,a2,...]) = [a,a0,a1/2,a2/3,...]}.
    lazyIntegrate  : (A,() -> ST A) -> ST A
      ++ lazyIntegrate(r,f) is a local function
      ++ used for fixed point computations.
    nlde       : ST ST A -> ST A
      ++ nlde(u) solves a
      ++ first order non-linear differential equation described by u of the
      ++ form \spad{[[b<0,0>,b<0,1>,...],[b<1,0>,b<1,1>,.],...]}.
      ++ the differential equation has the form
      ++ \spad{y' = sum(i=0 to infinity,j=0 to infinity,b<i,j>*(x**i)*(y**j))}.
    powern : (RN,ST A) -> ST A
      ++ powern(r,f) raises power series f to the power r.
  if A has Field then
    mapdiv     : (ST A,ST A) -> ST A
      ++ mapdiv([a0,a1,..],[b0,b1,..]) returns
      ++ \spad{[a0/b0,a1/b1,..]}.
    lazyGintegrate : (I -> A,A,() -> ST A) -> ST A
      ++ lazyGintegrate(f,r,g) is used for fixed point computations.
```

```
      power      : (A,ST A) -> ST A
        ++ power(a,f) returns the power series f raised to the power \spad{a}.

++ References:
++ Description:
++   StreamTranscendentalFunctions implements transcendental functions on
++   Taylor series, where a Taylor series is represented by a stream of
++   its coefficients.

 --% Exponentials and Logarithms
     exp     : ST -> ST
       ++ exp(st) computes the exponential of a power series st.
     log     : ST -> ST
       ++ log(st) computes the log of a power series.
     "**"    : (ST,ST) -> ST
       ++ st1 ** st2 computes the power of a power series st1 by another
       ++ power series st2.

 --% TrigonometricFunctionCategory
     sincos  : ST -> Record(sin:ST, cos:ST)
       ++ sincos(st) returns a record containing the sine and cosine
       ++ of a power series st.
     sin     : ST -> ST
       ++ sin(st) computes sine of a power series st.
     cos     : ST -> ST
       ++ cos(st) computes cosine of a power series st.
     tan     : ST -> ST
       ++ tan(st) computes tangent of a power series st.
     cot     : ST -> ST
       ++ cot(st) computes cotangent of a power series st.
     sec     : ST -> ST
       ++ sec(st) computes secant of a power series st.
     csc     : ST -> ST
       ++ csc(st) computes cosecant of a power series st.
     asin    : ST -> ST
       ++ asin(st) computes arcsine of a power series st.
     acos    : ST -> ST
       ++ acos(st) computes arccosine of a power series st.
     atan    : ST -> ST
       ++ atan(st) computes arctangent of a power series st.
     acot    : ST -> ST
       ++ acot(st) computes arccotangent of a power series st.
     asec    : ST -> ST
       ++ asec(st) computes arcsecant of a power series st.
     acsc    : ST -> ST
       ++ acsc(st) computes arccosecant of a power series st.

 --% HyperbloicTrigonometricFunctionCategory
     sinhcosh: ST -> Record(sinh:ST, cosh:ST)
       ++ sinhcosh(st) returns a record containing
       ++ the hyperbolic sine and cosine
       ++ of a power series st.
```

```
    sinh    : ST -> ST
      ++ sinh(st) computes the hyperbolic sine of a power series st.
    cosh    : ST -> ST
      ++ cosh(st) computes the hyperbolic cosine of a power series st.
    tanh    : ST -> ST
      ++ tanh(st) computes the hyperbolic tangent of a power series st.
    coth    : ST -> ST
      ++ coth(st) computes the hyperbolic cotangent of a power series st.
    sech    : ST -> ST
      ++ sech(st) computes the hyperbolic secant of a power series st.
    csch    : ST -> ST
      ++ csch(st) computes the hyperbolic cosecant of a power series st.
    asinh   : ST -> ST
      ++ asinh(st) computes the inverse hyperbolic sine of a power series st.
    acosh   : ST -> ST
      ++ acosh(st) computes the inverse hyperbolic cosine
      ++ of a power series st.
    atanh   : ST -> ST
      ++ atanh(st) computes the inverse hyperbolic tangent
      ++ of a power series st.
    acoth   : ST -> ST
      ++ acoth(st) computes the inverse hyperbolic
      ++ cotangent of a power series st.
    asech   : ST -> ST
      ++ asech(st) computes the inverse hyperbolic secant of a
      ++ power series st.
    acsch   : ST -> ST
      ++ acsch(st) computes the inverse hyperbolic
      ++ cosecant of a power series st.

--% Exponentials and Logarithms
    exp     : ST -> ST
      ++ exp(st) computes the exponential of a power series st.
    log     : ST -> ST
      ++ log(st) computes the log of a power series.
    "**"    : (ST,ST) -> ST
      ++ st1 ** st2 computes the power of a power series st1 by another
      ++ power series st2.

--% TrigonometricFunctionCategory
    sin     : ST -> ST
      ++ sin(st) computes sine of a power series st.
    cos     : ST -> ST
      ++ cos(st) computes cosine of a power series st.
    tan     : ST -> ST
      ++ tan(st) computes tangent of a power series st.
    cot     : ST -> ST
      ++ cot(st) computes cotangent of a power series st.
    sec     : ST -> ST
      ++ sec(st) computes secant of a power series st.
    csc     : ST -> ST
      ++ csc(st) computes cosecant of a power series st.
    asin    : ST -> ST
      ++ asin(st) computes arcsine of a power series st.
    acos    : ST -> ST
      ++ acos(st) computes arccosine of a power series st.
    atan    : ST -> ST
      ++ atan(st) computes arctangent of a power series st.
    acot    : ST -> ST
      ++ acot(st) computes arccotangent of a power series st.
    asec    : ST -> ST
      ++ asec(st) computes arcsecant of a power series st.
    acsc    : ST -> ST
      ++ acsc(st) computes arccosecant of a power series st.

--% HyperbloicTrigonometricFunctionCategory
    sinh    : ST -> ST
      ++ sinh(st) computes the hyperbolic sine of a power series st.
    cosh    : ST -> ST
      ++ cosh(st) computes the hyperbolic cosine of a power series st.
    tanh    : ST -> ST
      ++ tanh(st) computes the hyperbolic tangent of a power series st.
    coth    : ST -> ST
      ++ coth(st) computes the hyperbolic cotangent of a power series st.
    sech    : ST -> ST
      ++ sech(st) computes the hyperbolic secant of a power series st.
```

```
    csch    : ST -> ST
      ++ csch(st) computes the hyperbolic cosecant of a power series st.
    asinh   : ST -> ST
      ++ asinh(st) computes the inverse hyperbolic sine of a power series st.
    acosh   : ST -> ST
      ++ acosh(st) computes the inverse hyperbolic cosine
      ++ of a power series st.
    atanh   : ST -> ST
      ++ atanh(st) computes the inverse hyperbolic tangent
      ++ of a power series st.
    acoth   : ST -> ST
      ++ acoth(st) computes the inverse hyperbolic
      ++ cotangent of a power series st.
    asech   : ST -> ST
      ++ asech(st) computes the inverse hyperbolic secant of a
      ++ power series st.
    acsch   : ST -> ST
      ++ acsch(st) computes the inverse hyperbolic
      ++ cosecant of a power series st.

++ Subresultants
++ Author: Barry Trager, Renaud Rioboo
++ Date Created: 1987
++ Date Last Updated: August 2000
++ Description:
++ This package computes the subresultants of two polynomials which is needed
++ for the 'Lazard Rioboo' enhancement to Tragers integrations formula
++ For efficiency reasons this has been rewritten to call Lionel Ducos
++ package which is currently the best one.
++
SubResultantPackage(R, UP): Exports == Implementation where
  R : IntegralDomain
  UP: UnivariatePolynomialCategory R

  Z   ==> Integer
  N   ==> NonNegativeInteger

  Exports ==> with
    subresultantVector: (UP, UP) -> PrimitiveArray UP
      ++ subresultantVector(p, q) returns \spad{[p0,...,pn]}
      ++ where pi is the i-th subresultant of p and q.
      ++ In particular, \spad{p0 = resultant(p, q)}.
    if R has EuclideanDomain then
      primitivePart     : (UP,  R) -> UP
        ++ primitivePart(p, q) reduces the coefficient of p
        ++ modulo q, takes the primitive part of the result,
```

```
        ++ and ensures that the leading coefficient of that
        ++ result is monic.

++ Description:
++ Symbolic solver for systems of rational functions with coefficients
++ in an integral domain R.
++ The systems are solved in the field of rational functions over R.
++ Solutions are exact of the form variable = value when the value is
++ a member of the coefficient domain R. Otherwise the solutions
++ are implicitly expressed as roots of univariate polynomial equations over R.
++ Care is taken to guarantee that the denominators of the input
++ equations do not vanish on the solution sets.
++ The arguments to solve can either be given as equations or
++ as rational functions interpreted as equal
++ to zero. The user can specify an explicit list of symbols to
++ be solved for, treating all other symbols appearing as parameters
++ or omit the list of symbols in which case the system tries to
++ solve with respect to all symbols appearing in the input.

  public ==> with

--    IS THERE A WORKING DOMAIN Tableau ??
--    coerce : M I -> Tableau(I)
--      ++ coerce(ytab) coerces the Young-Tableau ytab to an element of
--      ++ the domain Tableau(I).

    coleman : (L I, L I, L I) -> M I
      ++ coleman(alpha,beta,pi):
      ++ there is a bijection from the set of matrices having nonnegative
      ++ entries and row sums {\em alpha}, column sums {\em beta}
      ++ to the set of {\em Salpha - Sbeta} double cosets of the
      ++ symmetric group {\em Sn}. ({\em Salpha} is the Young subgroup
      ++ corresponding to the improper partition {\em alpha}).
      ++ For a representing element {\em pi} of such a double coset,
      ++ coleman(alpha,beta,pi) generates the Coleman-matrix
      ++ corresponding to {\em alpha, beta, pi}.
      ++ Note: The permutation {\em pi} of {\em {1,2,...,n}} has to be given
      ++ in list form.
      ++ Note: the inverse of this map is {\em inverseColeman}
      ++ (if {\em pi} is the lexicographical smallest permutation
      ++ in the coset). For details see James/Kerber.
    inverseColeman : (L I, L I, M I) -> L I
      ++ inverseColeman(alpha,beta,C):
      ++ there is a bijection from the set of matrices having nonnegative
      ++ entries and row sums {\em alpha}, column sums {\em beta}
      ++ to the set of {\em Salpha - Sbeta} double cosets of the
      ++ symmetric group {\em Sn}. ({\em Salpha} is the Young subgroup
      ++ corresponding to the improper partition {\em alpha}).
```

```
  ++ For such a matrix C, inverseColeman(alpha,beta,C)
  ++ calculates the lexicographical smallest {\em pi} in the
  ++ corresponding double coset.
  ++ Note: the resulting permutation {\em pi} of {\em {1,2,...,n}}
  ++ is given in list form.
  ++ Notes: the inverse of this map is {\em coleman}.
  ++ For details, see James/Kerber.
listYoungTableaus : (L I) -> L M I
  ++ listYoungTableaus(lambda) where {\em lambda} is a proper partition
  ++ generates the list of all standard tableaus of shape {\em lambda}
  ++ by means of lattice permutations. The numbers of the lattice
  ++ permutation are interpreted as column labels. Hence the
  ++ contents of these lattice permutations are the conjugate of
  ++ {\em lambda}.
  ++ Notes: the functions {\em nextLatticePermutation} and
  ++ {\em makeYoungTableau} are used.
  ++ The entries are from {\em 0,...,n-1}.
makeYoungTableau : (L I,L I) -> M I
  ++ makeYoungTableau(lambda,gitter) computes for a given lattice
  ++ permutation {\em gitter} and for an improper partition {\em lambda}
  ++ the corresponding standard tableau of shape {\em lambda}.
  ++ Notes: see {\em listYoungTableaus}.
  ++ The entries are from {\em 0,...,n-1}.
nextColeman : (L I, L I, M I) -> M I
  ++ nextColeman(alpha,beta,C) generates the next Coleman matrix
  ++ of column sums {\em alpha} and row sums {\em beta} according
  ++ to the lexicographical order from bottom-to-top.
  ++ The first Coleman matrix is achieved by {\em C=new(1,1,0)}.
  ++ Also, {\em new(1,1,0)} indicates that C is the last Coleman matrix.
nextLatticePermutation : (L I, L I, B) -> L I
  ++ nextLatticePermutation(lambda,lattP,constructNotFirst) generates
  ++ the lattice permutation according to the proper partition
  ++ {\em lambda} succeeding the lattice permutation {\em lattP} in
  ++ lexicographical order as long as {\em constructNotFirst} is true.
  ++ If {\em constructNotFirst} is false, the first lattice permutation
  ++ is returned.
  ++ The result {\em nil} indicates that {\em lattP} has no successor.
nextPartition : (V I, V I, I) -> V I
  ++ nextPartition(gamma,part,number) generates the partition of
  ++ {\em number} which follows {\em part} according to the right-to-left
  ++ lexicographical order. The partition has the property that
  ++ its components do not exceed the corresponding components of
  ++ {\em gamma}. The first partition is achieved by {\em part=[]}.
  ++ Also, {\em []} indicates that {\em part} is the last partition.
nextPartition : (L I, V I, I) -> V I
  ++ nextPartition(gamma,part,number) generates the partition of
```

```
      ++ {\em number} which follows {\em part} according to the right-to-left
      ++ lexicographical order. The partition has the property that
      ++ its components do not exceed the corresponding components of
      ++ {\em gamma}. the first partition is achieved by {\em part=[]}.
      ++ Also, {\em []} indicates that {\em part} is the last partition.
    numberOfImproperPartitions: (I,I) -> I
      ++ numberOfImproperPartitions(n,m) computes the number of partitions
      ++ of the nonnegative integer n in m nonnegative parts with regarding
      ++ the order (improper partitions).
      ++ Example: {\em numberOfImproperPartitions (3,3)} is 10,
      ++ since {\em [0,0,3], [0,1,2], [0,2,1], [0,3,0], [1,0,2], [1,1,1],
      ++ [1,2,0], [2,0,1], [2,1,0], [3,0,0]} are the possibilities.
      ++ Note: this operation has a recursive implementation.
    subSet : (I,I,I) -> L I
      ++ subSet(n,m,k) calculates the {\em k}-th {\em m}-subset of the set
      ++ {\em 0,1,...,(n-1)} in the lexicographic order considered as
      ++ a decreasing map from {\em 0,...,(m-1)} into {\em 0,...,(n-1)}.
      ++ See S.G. Williamson: Theorem 1.60.
      ++ Error: if not {\em (0 <= m <= n and 0 < = k < (n choose m))}.
    unrankImproperPartitions0 : (I,I,I) -> L I
      ++ unrankImproperPartitions0(n,m,k) computes the {\em k}-th improper
      ++ partition of nonnegative n in m nonnegative parts in reverse
      ++ lexicographical order.
      ++ Example: {\em [0,0,3] < [0,1,2] < [0,2,1] < [0,3,0] <
      ++ [1,0,2] < [1,1,1] < [1,2,0] < [2,0,1] < [2,1,0] < [3,0,0]}.
      ++ Error: if k is negative or too big.
      ++ Note: counting of subtrees is done by
      ++ \spadfunFrom{numberOfImproperPartitions}{SymmetricGroupCombinatoricFunctions}.

    unrankImproperPartitions1: (I,I,I) -> L I
      ++ unrankImproperPartitions1(n,m,k) computes the {\em k}-th improper
      ++ partition of nonnegative n in at most m nonnegative parts
      ++ ordered as follows: first, in reverse
      ++ lexicographically according to their non-zero parts, then
      ++ according to their positions (i.e. lexicographical order
      ++ using {\em subSet}: {\em [3,0,0] < [0,3,0] < [0,0,3] < [2,1,0] <
      ++ [2,0,1] < [0,2,1] < [1,2,0] < [1,0,2] < [0,1,2] < [1,1,1]}).
      ++ Note: counting of subtrees is done by
      ++ {\em numberOfImproperPartitionsInternal}.

21.7 package UTSSOL TaylorSolve

UTSSOL is a facility to compute the first few coefficients of a Taylor series given only implicitely by a function f that vanishes when applied to the Taylor series.

It uses the method of undetermined coefficients.

```
Could I either
\begin{itemize}
\item take a function {\tt{}UTSCAT\ F\ ->\ UTSCAT\ F} and still be able to compute
  with undetermined coefficients, or
\item take a function {\tt{}F\ ->\ F}, and do likewise?
\end{itemize}

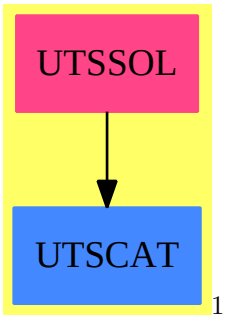
Let's see.

Try to compute the equation without resorting to power series. I.e., %
{\tt{}c:\ SUP\ SUP\ F}, and {\tt{}f:\ SUP\ SUP\ F\ ->\ SUP\ SUP\ F}. Won't this make the
computation of coefficients terribly slow?

I could also try to replace transcendental kernels with variables\dots

Unfortunately, {\tt{}SUP\ F} does not have {\tt{}TRANFUN} -- well, it can't, of
course. However, I'd like to be able to compute %
{\tt{}sin(1+monomial(1,1){\char36}UFPS\ SUP\ EXPR\ INT)}.
```

21.8 TaylorSolve



1.00

Exports:
seriesSolve

⟨*package UTSSOL TaylorSolve*⟩≡

```
)abbrev package UTSSOL TaylorSolve
TaylorSolve(F, UTSF, UTSSUPF): Exports == Implementation where
    F: Field
    SUP  ==> SparseUnivariatePolynomialExpressions
    UTSF: UnivariateTaylorSeriesCategory F
```

```
    UTSSUPF: UnivariateTaylorSeriesCategory SUP F
    NNI  ==> NonNegativeInteger

    Exports == with
        seriesSolve: (UTSSUPF -> UTSSUPF, List F) -> UTSF

    Implementation == add
```
⟨*implementation: UTSSOL TaylorSolve*⟩

⟨*implementation: UTSSOL TaylorSolve*⟩≡
```
        seriesSolve(f, l) ==
            c1 := map(#1::(SUP F), l)$ListFunctions2(F, SUP F)::(Stream SUP F)
            coeffs: Stream SUP F := concat(c1, generate(monomial(1$F,1$NNI)))
--            coeffs: Stream SUP F := concat(c1, monomial(1$F,1$NNI))
```

coeffs is the stream of the already computed coefficients of the solution, plus one which is so far undetermined. We store in st.2 the complete stream and in st.1 the stream starting with the first coefficient that has possibly not yet been computed.

```
The mathematics is not quite worked out. If {\tt{}coeffs} is initialized as
stream with all coefficients set to the \emph{same} transcendental value,
and not enough initial values are given, then the missing ones are
implicitely assumed to be all identical. It may well happen that a solution
is produced, although it is not uniquely determined\dots
```

⟨*implementation: UTSSOL TaylorSolve*⟩+≡
```
            st: List Stream SUP F := [coeffs, coeffs]
```

Consider an arbitrary equation $f\big(x, y(x)\big) = 0$. When setting $x = 0$, we obtain $f\big(0, y(0)\big) = 0$. It is not necessarily the case that this determines $y(0)$ uniquely, so we need one initial value that satisfies this equation.

```
{\tt{}seriesSolve} should check that the given initial values satisfy $f\big(0, y(0),
y'(0),...\big) = 0$.
```

Now consider the derivatives of f, where we write y instead of $y(x)$ for better readability:

$$\frac{d}{dx} f(x, y) = f_1(x, y) + f_2(x, y)y'$$

and

```
\frac{d^2}{dx^2}f(x, y)&=f_{1,1}(x, y)\\
                       &+f_{1,2}(x, y)y^\prime\\
                       &+f_{2,1}(x, y)y^\prime\\
                       &+f_{2,2}(x, y)(y^\prime)^2\\
                       &+f_2(x, y)y^{\prime\prime}.
```

In general, $\frac{d^2}{dx^2} f(x, y)$ depends only linearly on y''.

```
This points to another possibility: Since we know that we only need to solve
linear equations, we could compute two values and then use interpolation.
This might be a bit slower, but more importantly: can we still check that we
have enough initial values? Furthermore, we then really need that $f$ is
analytic, i.e., operators are not necessarily allowed anymore. However, it
seems that composition is allowed.
```

⟨*implementation: UTSSOL TaylorSolve*⟩+≡

```
            next: () -> F :=
                nr := st.1
                res: F

                if ground?(coeff: SUP F := nr.1)$(SUP F)
```

If the next element was already calculated, we can simply return it:

⟨*implementation: UTSSOL TaylorSolve*⟩+≡

```
                then
                    res := ground coeff
                    st.1 := rest nr
                else
```

Otherwise, we have to find the first non-satisfied relation and solve it. It should be linear, or a single non-constant monomial. That is, the solution should be unique.

⟨*implementation: UTSSOL TaylorSolve*⟩+≡

```
                    ns := st.2
                    eqs: Stream SUP F := coefficients f series ns
                    while zero? first eqs repeat eqs := rest eqs
                    eq: SUP F := first eqs
                    if degree eq > 1 then
                        if monomial? eq then res := 0
                        else
                            output(hconcat("The equation is: ", eq::OutputForm))
                                  $OutputPackage
                            error "seriesSolve: equation for coefficient not line
                    else res := (-coefficient(eq, 0$NNI)$(SUP F)
                                 /coefficient(eq, 1$NNI)$(SUP F))

                    nr.1 := res::SUP F
--                    concat!(st.2, monomial(1$F,1$NNI))
                    st.1 := rest nr

                res

            series generate next

Implementation ==> add
```

I have had to work my way around the following bug in the compiler: When a local variable is given a mapping as a value, e.g.

```
foo : SF -> SF := makeFloatFunction(f,t),
```

the compiler cannot distinguish that local variable from a local function defined elsewhere in the package. Thus, when 'foo' is passed to a function, e.g.

```
bird := fcn(foo),
```

foo will often be compiled as `|DRAW;foo|` rather than `|foo|`. This, of course, causes a run-time error.

To avoid this problem, local variables are not given mappings as values, but rather (singleton) lists of mappings. The first element of the list can always be extracted and everything goes through as before. There is no major loss in efficiency, as the computation of points will always dominate the computation time.

The function myTrap1 is a local function for used in creating maps SF -¿ Point SF (two dimensional). The range of this function is SingleFloat. As originally coded it would return $NaNvalue$Lisp which is outside the range. Since this function is only used internallly by the draw package we handle the "failed" case by returning zero. We handle the out-of-range case by returning the maximum or minimum SingleFloat value.

    Exports ==> with
      expand     : F -> F
        ++ expand(f) performs the following expansions on f:\begin{items}
        ++ \item 1. logs of products are expanded into sums of logs,
        ++ \item 2. trigonometric and hyperbolic trigonometric functions
        ++ of sums are expanded into sums of products of trigonometric
        ++ and hyperbolic trigonometric functions.
        ++ \item 3. formal powers of the form \spad{(a/b)**c} are expanded into
        ++ \spad{a**c * b**(-c)}.
        ++ \end{items}
      simplify   : F -> F
        ++ simplify(f) performs the following simplifications on f:\begin{items}
        ++ \item 1. rewrites trigs and hyperbolic trigs in terms
        ++ of \spad{sin} ,\spad{cos}, \spad{sinh}, \spad{cosh}.
        ++ \item 2. rewrites \spad{sin**2} and \spad{sinh**2} in terms
        ++ of \spad{cos} and \spad{cosh},
        ++ \item 3. rewrites \spad{exp(a)*exp(b)} as \spad{exp(a+b)}.
        ++ \item 4. rewrites \spad{(a**(1/n))**m * (a**(1/s))**t} as a single
        ++ power of a single radical of \spad{a}.
        ++ \end{items}
      htrigs     : F -> F
        ++ htrigs(f) converts all the exponentials in f into
        ++ hyperbolic sines and cosines.
      simplifyExp: F -> F
        ++ simplifyExp(f) converts every product \spad{exp(a)*exp(b)}
        ++ appearing in f into \spad{exp(a+b)}.
      simplifyLog : F -> F
        ++ simplifyLog(f) converts every \spad{log(a) - log(b)} appearing in f
        ++ into \spad{log(a/b)}, every \spad{log(a) + log(b)} into \spad{log(a*b)}
        ++ and every \spad{n*log(a)} into \spad{log(a^n)}.
      expandPower: F -> F
        ++ expandPower(f) converts every power \spad{(a/b)**c} appearing
        ++ in f into \spad{a**c * b**(-c)}.
      expandLog  : F -> F
        ++ expandLog(f) converts every \spad{log(a/b)} appearing in f into
        ++ \spad{log(a) - log(b)}, and every \spad{log(a*b)} into
        ++ \spad{log(a) + log(b)}..
      cos2sec    : F -> F
        ++ cos2sec(f) converts every \spad{cos(u)} appearing in f into
        ++ \spad{1/sec(u)}.
      cosh2sech  : F -> F
```

```
    ++ cosh2sech(f) converts every \spad{cosh(u)} appearing in f into
    ++ \spad{1/sech(u)}.
  cot2trig   : F -> F
    ++ cot2trig(f) converts every \spad{cot(u)} appearing in f into
    ++ \spad{cos(u)/sin(u)}.
  coth2trigh : F -> F
    ++ coth2trigh(f) converts every \spad{coth(u)} appearing in f into
    ++ \spad{cosh(u)/sinh(u)}.
  csc2sin    : F -> F
    ++ csc2sin(f) converts every \spad{csc(u)} appearing in f into
    ++ \spad{1/sin(u)}.
  csch2sinh  : F -> F
    ++ csch2sinh(f) converts every \spad{csch(u)} appearing in f into
    ++ \spad{1/sinh(u)}.
  sec2cos    : F -> F
    ++ sec2cos(f) converts every \spad{sec(u)} appearing in f into
    ++ \spad{1/cos(u)}.
  sech2cosh  : F -> F
    ++ sech2cosh(f) converts every \spad{sech(u)} appearing in f into
    ++ \spad{1/cosh(u)}.
  sin2csc    : F -> F
    ++ sin2csc(f) converts every \spad{sin(u)} appearing in f into
    ++ \spad{1/csc(u)}.
  sinh2csch  : F -> F
    ++ sinh2csch(f) converts every \spad{sinh(u)} appearing in f into
    ++ \spad{1/csch(u)}.
  tan2trig   : F -> F
    ++ tan2trig(f) converts every \spad{tan(u)} appearing in f into
    ++ \spad{sin(u)/cos(u)}.
  tanh2trigh : F -> F
    ++ tanh2trigh(f) converts every \spad{tanh(u)} appearing in f into
    ++ \spad{sinh(u)/cosh(u)}.
  tan2cot    : F -> F
    ++ tan2cot(f) converts every \spad{tan(u)} appearing in f into
    ++ \spad{1/cot(u)}.
  tanh2coth  : F -> F
    ++ tanh2coth(f) converts every \spad{tanh(u)} appearing in f into
    ++ \spad{1/coth(u)}.
  cot2tan    : F -> F
    ++ cot2tan(f) converts every \spad{cot(u)} appearing in f into
    ++ \spad{1/tan(u)}.
  coth2tanh  : F -> F
    ++ coth2tanh(f) converts every \spad{coth(u)} appearing in f into
    ++ \spad{1/tanh(u)}.
  removeCosSq: F -> F
    ++ removeCosSq(f) converts every \spad{cos(u)**2} appearing in f into
```

```
      ++ \spad{1 - sin(x)**2}, and also reduces higher
      ++ powers of \spad{cos(u)} with that formula.
    removeSinSq: F -> F
      ++ removeSinSq(f) converts every \spad{sin(u)**2} appearing in f into
      ++ \spad{1 - cos(x)**2}, and also reduces higher powers of
      ++ \spad{sin(u)} with that formula.
    removeCoshSq:F -> F
      ++ removeCoshSq(f) converts every \spad{cosh(u)**2} appearing in f into
      ++ \spad{1 - sinh(x)**2}, and also reduces higher powers of
      ++ \spad{cosh(u)} with that formula.
    removeSinhSq:F -> F
      ++ removeSinhSq(f) converts every \spad{sinh(u)**2} appearing in f into
      ++ \spad{1 - cosh(x)**2}, and also reduces higher powers
      ++ of \spad{sinh(u)} with that formula.
    if R has PatternMatchable(R) and R has ConvertibleTo(Pattern(R)) and F has Co
      expandTrigProducts : F -> F
        ++ expandTrigProducts(e) replaces \axiom{sin(x)*sin(y)} by
        ++ \spad{(cos(x-y)-cos(x+y))/2}, \axiom{cos(x)*cos(y)} by
        ++ \spad{(cos(x-y)+cos(x+y))/2}, and \axiom{sin(x)*cos(y)} by
        ++ \spad{(sin(x-y)+sin(x+y))/2}.  Note that this operation uses
        ++ the pattern matcher and so is relatively expensive.  To avoid
        ++ getting into an infinite loop the transformations are applied
        ++ at most ten times.

)abbrev package SOLVETRA TransSolvePackage
++ Author: W. Wiwianka, Martin Rubey
++ Date Created: Summer 1991
++ Change History: 9/91
++ Basic Operations: solve
++ Related Constructors: RadicalSolvePackage, FloatingRealPackage
++ Keywords:
++ Description:
++  This package tries to find solutions of equations of type Expression(R).
++  This means expressions involving transcendental, exponential, logarithmic
++  and nthRoot functions.
++  After trying to transform different kernels to one kernel by applying
++  several rules, it calls zerosOf for the SparseUnivariatePolynomial in
++  the remaining kernel.
++  For example the expression  \spad{sin(x)*cos(x)-2}  will be transformed to
++     \spad{-2 tan(x/2)**4 -2 tan(x/2)**3 -4 tan(x/2)**2 +2 tan(x/2) -2}
++  by  using the function  normalize  and then to
++     \spad{-2 tan(x)**2 + tan(x) -2}
++  with help of subsTan. This function tries to express the given function
++  in terms of \spad{tan(x/2)}  to express in terms of \spad{tan(x)} .
++  Other examples are the expressions    \spad{sqrt(x+1)+sqrt(x+7)+1}   or
++   \spad{sqrt(sin(x))+1} .

++ Fraction free inverses of triangular matrices
++ Author: Victor Miller
++ Date Created:
++ Date Last Updated: 24 Jul 1990
++ Keywords:
++ Examples:
++ References:
++ Description:
++ This package provides functions that compute "fraction-free"
++ inverses of upper and lower triangular matrices over a integral
++ domain.  By "fraction-free inverses" we mean the following:
++ given a matrix B with entries in R and an element d of R such that
++ d * inv(B) also has entries in R, we return d * inv(B).  Thus,
++ it is not necessary to pass to the quotient field in any of our
++ computations.

TriangularMatrixOperations(R,Row,Col,M): Exports == Implementation where
  R   : IntegralDomain
  Row : FiniteLinearAggregate R
  Col : FiniteLinearAggregate R
  M   : MatrixCategory(R,Row,Col)

++ Description:
++   Tools for constructing tubes around 3-dimensional parametric curves.
TubePlotTools(): Exports == Implementation where
  I   ==> Integer
  SF  ==> DoubleFloat
  L   ==> List
  Pt  ==> Point SF

  Exports ==> with
    point: (SF,SF,SF,SF) -> Pt
      ++ point(x1,x2,x3,c) creates and returns a point from the three
      ++ specified coordinates \spad{x1}, \spad{x2}, \spad{x3}, and also
      ++ a fourth coordinate, c, which is generally used to specify the
      ++ color of the point.
    "*" : (SF,Pt) -> Pt
      ++ s * p returns a point whose coordinates are the scalar multiple
      ++ of the point p by the scalar s, preserving the color, or fourth
      ++ coordinate, of p.
    "+" : (Pt,Pt) -> Pt
      ++ p + q computes and returns a point whose coordinates are the sums
```

```
      ++ of the coordinates of the two points \spad{p} and \spad{q}, using
      ++ the color, or fourth coordinate, of the first point \spad{p}
      ++ as the color also of the point \spad{q}.
    "-" : (Pt,Pt) -> Pt
      ++ p - q computes and returns a point whose coordinates are the
      ++ differences of the coordinates of two points \spad{p} and \spad{q},
      ++ using the color, or fourth coordinate, of the first point \spad{p}
      ++ as the color also of the point \spad{q}.
    dot : (Pt,Pt) -> SF
      ++ dot(p,q) computes the dot product of the two points \spad{p}
      ++ and \spad{q} using only the first three coordinates, and returns
      ++ the resulting \spadtype{DoubleFloat}.
    cross : (Pt,Pt) -> Pt
      ++ cross(p,q) computes the cross product of the two points \spad{p}
      ++ and \spad{q} using only the first three coordinates, and keeping
      ++ the color of the first point p.  The result is returned as a point.
    unitVector: Pt -> Pt
      ++ unitVector(p) creates the unit vector of the point p and returns
      ++ the result as a point.  Note: \spad{unitVector(p) = p/|p|}.
    cosSinInfo: I -> L L SF
      ++ cosSinInfo(n) returns the list of lists of values for n, in the
      ++ form:  \spad{[[cos(n - 1) a,sin(n - 1) a],...,[cos 2 a,sin 2 a],[cos a,s
      ++ where \spad{a = 2 pi/n}.  Note: n should be greater than 2.
    loopPoints: (Pt,Pt,Pt,SF,L L SF) -> L Pt
      ++ loopPoints(p,n,b,r,lls) creates and returns a list of points
      ++ which form the loop with radius r, around the center point
      ++ indicated by the point p, with the principal normal vector of
      ++ the space curve at point p given by the point(vector) n, and the
      ++ binormal vector given by the point(vector) b, and a list of lists,
      ++ lls, which is the \spadfun{cosSinInfo} of the number of points
      ++ defining the loop.

  Pt     ==> Point DoubleFloat
  PLOT   ==> Plot
  CLIPPED ==> Record(brans: L L Pt,xValues: SEG SF,yValues: SEG SF)

  Exports ==> with
    clip: PLOT -> CLIPPED
      ++ clip(p) performs two-dimensional clipping on a plot, p, from
      ++ the domain \spadtype{Plot} for the graph of one variable,
      ++ \spad{y = f(x)}; the default parameters \spad{1/4} for the fraction
```

```
      ++ and \spad{5/1} for the scale are used in the \spadfun{clip} function.
    clip: (PLOT,RN,RN) -> CLIPPED
      ++ clip(p,frac,sc) performs two-dimensional clipping on a plot, p,
      ++ from the domain \spadtype{Plot} for the graph of one variable
      ++ \spad{y = f(x)}; the fraction parameter is specified by \spad{frac}
      ++ and the scale parameter is specified by \spad{sc} for use in the
      ++ \spadfun{clip} function.
    clipParametric: PLOT -> CLIPPED
      ++ clipParametric(p) performs two-dimensional clipping on a plot,
      ++ p, from the domain \spadtype{Plot} for the parametric curve
      ++ \spad{x = f(t)}, \spad{y = g(t)}; the default parameters \spad{1/2}
      ++ for the fraction and \spad{5/1} for the scale are used in the
      ++ \fakeAxiomFun{iClipParametric} subroutine, which is called by this
      ++ function.
    clipParametric: (PLOT,RN,RN) -> CLIPPED
      ++ clipParametric(p,frac,sc) performs two-dimensional clipping on a
      ++ plot, p, from the domain \spadtype{Plot} for the parametric curve
      ++ \spad{x = f(t)}, \spad{y = g(t)}; the fraction parameter is
      ++ specified by \spad{frac} and the scale parameter is specified
      ++ by \spad{sc} for use in the \fakeAxiomFun{iClipParametric} subroutine,
      ++ which is called by this function.
    clipWithRanges: (L L Pt,SF,SF,SF,SF) -> CLIPPED
      ++ clipWithRanges(pointLists,xMin,xMax,yMin,yMax) performs clipping
      ++ on a list of lists of points, \spad{pointLists}.  Clipping is
      ++ done within the specified ranges of \spad{xMin}, \spad{xMax} and
      ++ \spad{yMin}, \spad{yMax}.  This function is used internally by
      ++ the \fakeAxiomFun{iClipParametric} subroutine in this package.
    clip: L Pt -> CLIPPED
      ++ clip(l) performs two-dimensional clipping on a curve l, which is
      ++ a list of points; the default parameters \spad{1/2} for the
      ++ fraction and \spad{5/1} for the scale are used in the
      ++ \fakeAxiomFun{iClipParametric} subroutine, which is called by this
      ++ function.
    clip: L L Pt -> CLIPPED
      ++ clip(ll) performs two-dimensional clipping on a list of lists
      ++ of points, \spad{ll}; the default parameters \spad{1/2} for
      ++ the fraction and \spad{5/1} for the scale are used in the
      ++ \fakeAxiomFun{iClipParametric} subroutine, which is called by this
      ++ function.

++ Description:
++ A basic package for the factorization of bivariate polynomials
++ over a finite field.
++ The functions here represent the base step for the multivariate factorizer.

TwoFactorize(F) : C == T
 where
  F           :   FiniteFieldCategory
  SUP         ==>  SparseUnivariatePolynomial
  R           ==>  SUP F
  P           ==>  SUP R
  UPCF2       ==>  UnivariatePolynomialCategoryFunctions2

  C == with
    generalTwoFactor    : (P)  ->  Factored P
      ++ generalTwoFactor(p) returns the factorisation of polynomial p,
      ++ a sparse univariate polynomial (sup) over a
      ++ sup over F.
    generalSqFr    : (P)  ->  Factored P
      ++ generalSqFr(p) returns the square-free factorisation of polynomial p,
      ++ a sparse univariate polynomial (sup) over a
      ++ sup over F.
    twoFactor    : (P,Integer)  ->  Factored P
```

```
      ++ twoFactor(p,n) returns the factorisation of polynomial p,
      ++ a sparse univariate polynomial (sup) over a
      ++ sup over F.
      ++ Also, p is assumed primitive and square-free and n is the
      ++ degree of the inner variable of p (maximum of the degrees
      ++ of the coefficients of p).

++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ This package provides for square-free decomposition of
++ univariate polynomials over arbitrary rings, i.e.
++ a partial factorization such that each factor is a product
++ of irreducibles with multiplicity one and the factors are
++ pairwise relatively prime. If the ring
++ has characteristic zero, the result is guaranteed to satisfy
++ this condition. If the ring is an infinite ring of
++ finite characteristic, then it may not be possible to decide when
++ polynomials contain factors which are pth powers. In this
++ case, the flag associated with that polynomial is set to "nil"
++ (meaning that that polynomials are not guaranteed to be square-free).

UnivariatePolynomialSquareFree(RC:IntegralDomain,P):C == T

27.1 package ZDSOLVE ZeroDimensionalSolvePackage

Based on triangular decompositions and the **RealClosure** constructor, the pacakge **ZeroDimensionalSolvePackage** provides operations for computing symbolically the real or complex roots of polynomial systems with finitely many solutions.

==========================================================================
ZeroDimensionalSolvePackage examples
==========================================================================

The ZeroDimensionalSolvePackage package constructor provides
operations for computing symbolically the complex or real roots of
zero-dimensional algebraic systems.

The package provides no multiplicity information (i.e. some returned
roots may be double or higher) but only distinct roots are returned.

Complex roots are given by means of univariate representations of
irreducible regular chains.  These representations are computed by the
univariateSolve operation (by calling the
InternalRationalUnivariateRepresentationPackage package constructor
which does the job).

Real roots are given by means of tuples of coordinates lying in the
RealClosure of the coefficient ring.  They are computed by the
realSolve and positiveSolve operations.  The former computes all the
solutions of the input system with real coordinates whereas the later
concentrate on the solutions with (strictly) positive coordinates.  In
both cases, the computations are performed by the RealClosure constructor.

Both computations of complex roots and real roots rely on triangular
decompositions.  These decompositions can be computed in two different
ways.  First, by a applying the zeroSetSplit operation from the REGSET
domain constructor.  In that case, no Groebner bases are computed.
This strategy is used by default.  Secondly, by applying the zeroSetSplit
from LEXTRIPK.  To use this later strategy with the operations
univariateSolve, realSolve and positiveSolve one just needs to use an
extra boolean argument.

Note that the way of understanding triangular decompositions is
detailed in the example of the RegularTriangularSet constructor.

The ZeroDimensionalSolvePackage constructor takes three arguments.The
first one R is the coefficient ring; it must belong to the categories
OrderedRing, EuclideanDomain, CharacteristicZero and RealConstant. This
means essentially that R is Integer or Fraction(Integer).  The second
argument ls is the list of variables involved in the systems to solve.
The third one MUST BE concat(ls,s) where s is an additional symbol used
for the univariate representations. The abbreviation for
ZeroDimensionalSolvePackage is ZDSOLVE.
```

We illustrate now how to use the constructor ZDSOLVE by two examples: the Arnborg and Lazard system and the L-3 system (Aubry and Moreno Maza). Note that the use of this package is also demonstrated in the example of the LexTriangularPackage constructor.

Define the coefficient ring.

```
R := Integer
  Integer
                        Type: Domain
```

Define the lists of variables:

```
ls : List Symbol := [x,y,z,t]
  [x,y,z,t]
                        Type: List Symbol
```

and:

```
ls2 : List Symbol := [x,y,z,t,new()$Symbol]
  [x,y,z,t,%A]
                        Type: List Symbol
```

Call the package:

```
pack := ZDSOLVE(R,ls,ls2)
  ZeroDimensionalSolvePackage(Integer,[x,y,z,t],[x,y,z,t,%A])
                        Type: Domain
```

Define a polynomial system (Arnborg-Lazard)

```
p1 := x**2*y*z + x*y**2*z + x*y*z**2 + x*y*z + x*y + x*z + y*z
       2       2     2
  x y z  + (x y  + (x  + x + 1)y + x)z + x y
                        Type: Polynomial Integer

p2 := x**2*y**2*z + x*y**2*z**2 + x**2*y*z + x*y*z + y*z + x + z
     2 2     2 2     2
  x y z  + (x y  + (x  + x + 1)y + 1)z + x
                        Type: Polynomial Integer

p3 := x**2*y**2*z**2 + x**2*y**2*z + x*y**2*z + x*y*z + x*z + z + 1
   2 2 2      2      2
  x y z  + ((x  + x)y  + x y + x + 1)z + 1
                        Type: Polynomial Integer
```

```
lp := [p1, p2, p3]
       2       2     2
 [x y z  + (x y  + (x  + x + 1)y + x)z + x y,
     2 2     2 2     2
  x y z  + (x y  + (x  + x + 1)y + 1)z + x,
   2 2 2       2      2
  x y z  + ((x  + x)y  + x y + x + 1)z + 1]
                      Type: List Polynomial Integer
```

Note that these polynomials do not involve the variable t; we will use it in the second example.

First compute a decomposition into regular chains (i.e. regular triangular sets).

```
triangSolve(lp)$pack
 [
  {
       20     19      18      17       16      15       14       13       12

        - 62378085z  - 55776527z  - 33940618z  - 42233406z  - 21122875z
      +
                  4            3           2
        - 22958177z  - 13504569z  + 8448317z  + 1195888z - 202934
      ,
        3       2       3    2              2              2
       ((z  - 2z)y  + (- z  - z  - 2z - 1)y - z  - z + 1)x + z  - 1}
     ]
                      Type: List RegularChain(Integer,[x,y,z,t])
```

We can see easily from this decomposition (consisting of a single regular chain) that the input system has 20 complex roots.

Then we compute a univariate representation of this regular chain.

```
  univariateSolve(lp)$pack

                            coordinates: List Polynomial Integer)
```

We see that the zeros of our regular chain are split into three components. This is due to the use of univariate polynomial factorization.

Each of these components consist of two parts. The first one is an irreducible univariate polynomial p(?) which defines a simple algebraic extension of the field of fractions of R. The second one consists of multivariate polynomials pol1(x,%A), pol2(y,%A) and pol3(z,%A). Each of these polynomials involve two variables: one is an indeterminate x, y or z of the input system lp and the other is %A which represents any root of p(?). Recall that this %A is the last element of the third parameter of ZDSOLVE. Thus any complex root ? of p(?) leads to a solution of the input system lp by replacing %A by this ? in pol1(x,%A), pol2(y,%A) and pol3(z,%A). Note that the polynomials pol1(x,%A), pol2(y,%A) and pol3(z,%A) have degree one w.r.t. x, y or z respectively. This is always the case for all univariate representations. Hence the operation univariateSolve replaces a system of multivariate polynomials by a list of univariate polynomials, what justifies its name. Another example of univariate representations illustrates the LexTriangularPackage package constructor.

We now compute the solutions with real coordinates:

```
  lr := realSolve(lp)$pack

       ]
     ]
                    Type: List List RealClosure Fraction Integer

  The number of real solutions for the input system is:

    # lr
      8
                    Type: PositiveInteger

  Each of these real solutions is given by a list of elements in
  RealClosure(R).  In these 8 lists, the first element is a value of z,
  the second of y and the last of x.  This is logical since by setting
  the list of variables of the package to [x,y,z,t] we mean that the
  elimination ordering on the variables is t < z < y < x.  Note that
  each system treated by the ZDSOLVE package constructor needs only to
  be zero-dimensional w.r.t. the variables involved in the system it-self
  and not necessarily w.r.t. all the variables used to define the package.

  We can approximate these real numbers as follows.  This computation
  takes between 30 sec. and 5 min, depending on your machine.

    [ [approximate(r,1/1000000) for r in point] for point in lr]

            6574997982787261696305321767320171723725209 6
       ]
     ]
                        Type: List List Fraction Integer
```

We can also concentrate on the solutions with real (strictly) positive coordinates:

```
  lpr := positiveSolve(lp)$pack
    []
                        Type: List List RealClosure Fraction Integer
```

Thus we have checked that the input system has no solution with strictly positive coordinates.

Let us define another polynomial system (L-3).

```
  f0 := x**3 + y + z + t- 1
              3
     z + y + x  + t - 1
                      Type: Polynomial Integer

  f1 := x + y**3 + z + t -1
          3
     z + y  + x + t - 1
                      Type: Polynomial Integer

  f2 := x + y + z**3 + t-1
      3
```

```
      z  + y + x + t - 1
                        Type: Polynomial Integer

   f3 := x + y + z + t**3 -1
                    3
      z + y + x + t  - 1
                        Type: Polynomial Integer

   lf := [f0, f1, f2, f3]
             3              3              3                                3
   [z + y + x  + t - 1,z + y  + x + t - 1,z  + y + x + t - 1,z + y + x + t  - 1]
                        Type: List Polynomial Integer
```

First compute a decomposition into regular chains (i.e. regular triangular sets).

```
   lts := triangSolve(lf)$pack
   [
       2           3        3
     {t  + t + 1, z  - z - t  + t,
                  3      2      2      3           6     3            3      2
         (3z + 3t  - 3)y  + (3z  + (6t  - 6)z + 3t  - 6t  + 3)y + (3t  - 3)z
       +
            6     3          9     6     3
         (3t  - 6t  + 3)z + t  - 3t  + 5t  - 3t
       ,
        x + y + z}

Note that this computation is made from the input system lf.

However it is possible to reuse a pre-computed regular chain as follows:

```
ts := lts.1
   2          3        3
 {t  + t + 1, z  - z - t  + t,

              3      2      2      3           6     3            3      2
      (3z + 3t  - 3)y  + (3z  + (6t  - 6)z + 3t  - 6t  + 3)y + (3t  - 3)z
   +
        6     3          9     6     3
      (3t  - 6t  + 3)z + t  - 3t  + 5t  - 3t
   ,
  x + y + z}
                     Type: RegularChain(Integer,[x,y,z,t])

univariateSolve(ts)$pack

            1     3   1   1     3   1   1     3   1
    [%B18,- - %B18  + -,- - %B18  + -,- - %B18  + -]]
            3         3   3         3   3         3
                        Type: List List RealClosure Fraction Integer
```

The number of real solutions for the input system is:

```
  #lr2
    27
                                Type: PositiveInteger
```

Another example of computation of real solutions illustrates the LexTriangularPackage package constructor.

We concentrate now on the solutions with real (strictly) positive coordinates:

```
  lpr2 := positiveSolve(lf)$pack
              1     3   1   1     3   1   1     3   1
     [[%B40,- - %B40  + -,- - %B40  + -,- - %B40  + -]]
              3         3   3         3   3         3
                              Type: List List RealClosure Fraction Integer
```

```
Finally, we approximate the coordinates of this point with 20 exact digits:

  [approximate(r,1/10**21)::Float for r in lpr2.1]
   [0.3221853546 2608559291, 0.3221853546 2608559291, 0.3221853546 2608559291,
    0.3221853546 2608559291]
                              Type: List Float

++ Description:
++   A package for computing symbolically the complex and real roots of
++   zero-dimensional algebraic systems over the integer or rational
++   numbers. Complex roots are given by means of univariate representations
++   of irreducible regular chains. Real roots are given by means of tuples
++   of coordinates lying in the \spadtype{RealClosure} of the coefficient ring.
++   This constructor takes three arguments. The first one \spad{R} is the
++   coefficient ring. The second one \spad{ls} is the list of variables involved
++   in the systems to solve. The third one must be \spad{concat(ls,s)} where
++   \spad{s} is an additional symbol used for the univariate representations.
++   WARNING: The third argument is not checked.
++   All operations are based on triangular decompositions.
++   The default is to compute these decompositions directly from the input
++   system by using the \spadtype{RegularChain} domain constructor.
++   The lexTriangular algorithm can also be used for computing these decompositions
++   (see the \spadtype{LexTriangularPackage} package constructor).
++   For that purpose, the operations \axiomOpFrom{univariateSolve}{ZeroDimensionalSolvePack
++   \axiomOpFrom{realSolve}{ZeroDimensionalSolvePackage} and
++   \axiomOpFrom{positiveSolve}{ZeroDimensionalSolvePackage} admit an optional
++   argument. \newline Author: Marc Moreno Maza.

  Exports ==  with
     triangSolve: (LP,B,B) -> List RegularChain(R,ls)
       ++ \spad{triangSolve(lp,info?,lextri?)} decomposes the variety
       ++ associated with \axiom{lp} into regular chains.
       ++ Thus a point belongs to this variety iff it is a regular
       ++ zero of a regular set in in the output.
       ++ Note that \axiom{lp} needs to generate a zero-dimensional ideal.
       ++ If \axiom{lp} is not zero-dimensional then the result is only
       ++ a decomposition of its zero-set in the sense of the closure
       ++ (w.r.t. Zarisky topology).
```

```
    ++ Moreover, if \spad{info?} is \spad{true} then some information is
    ++ displayed during the computations.
    ++ See \axiomOpFrom{zeroSetSplit}{RegularTriangularSetCategory}(lp,true,info?).
    ++ If \spad{lextri?} is \spad{true} then the lexTriangular algorithm is called
    ++ from the \spadtype{LexTriangularPackage} constructor
    ++ (see \axiomOpFrom{zeroSetSplit}{LexTriangularPackage}(lp,false)).
    ++ Otherwise, the triangular decomposition is computed directly from the input
    ++ system by using the \axiomOpFrom{zeroSetSplit}{RegularChain} from \spadtype{Regula
  triangSolve: (LP,B) -> List RegularChain(R,ls)
    ++ \spad{triangSolve(lp,info?)} returns the same as \spad{triangSolve(lp,false)}
  triangSolve: LP -> List RegularChain(R,ls)
    ++ \spad{triangSolve(lp)} returns the same as \spad{triangSolve(lp,false,false)}
  univariateSolve: RegularChain(R,ls) -> List Record(complexRoots: U, coordinates: LP)
    ++ \spad{univariateSolve(ts)} returns a univariate representation
    ++ of \spad{ts}.
    ++ See \axiomOpFrom{rur}{RationalUnivariateRepresentationPackage}(lp,true).
  univariateSolve: (LP,B,B,B) -> List RUR
    ++ \spad{univariateSolve(lp,info?,check?,lextri?)} returns a univariate
    ++ representation of the variety associated with \spad{lp}.
    ++ Moreover, if \spad{info?} is \spad{true} then some information is
    ++ displayed during the decomposition into regular chains.
    ++ If \spad{check?} is \spad{true} then the result is checked.
    ++ See \axiomOpFrom{rur}{RationalUnivariateRepresentationPackage}(lp,true).
    ++ If \spad{lextri?} is \spad{true} then the lexTriangular algorithm is called
    ++ from the \spadtype{LexTriangularPackage} constructor
    ++ (see \axiomOpFrom{zeroSetSplit}{LexTriangularPackage}(lp,false)).
