1   Module Arg : Parsing of command line arguments.

This module provides a general mechanism for extracting options and arguments from the command line to the program.

   Syntax of command lines: A keyword is a character string starting with a- . An option is a keyword alone or followed by an argument. The types of keywords areUnit , Bool, Set, Clear , String , Set_string , Int , Set_int , Float , Set_float , Tuple, Symbol, and Rest. Unit , Set and Clear keywords take no argument. A Rest keyword takes the remaining of the command line as arguments. Every other keyword takes the following word on the command line as argument. Arguments not preceded by a keyword are called anonymous arguments.

   Examples (cmdis assumed to be the command name):

- cmd -flag   (a unit option)

- cmd -int 1   (an int option with argument 1)

- cmd -string foobar   (a string option with argument "foobar")

- cmd -float 12.34   (a oat option with argument 12.34)

- cmd a b c(three anonymous arguments:"a" , "b" , and "c")

- cmd a b   c d (two anonymous arguments and a rest option with two arguments)

```
type  spec =
  | Unit of (unit -> unit)
          Call the function with unit argument
  | Bool of (bool -> unit)
          Call the function with a bool argument
  | Set of bool Pervasives.ref
          Set the reference to true
  | Clear of bool Pervasives.ref
          Set the reference to false
  | String of (string -> unit)
          Call the function with a string argument
  | Set_string of string Pervasives.ref
```

3

Set the reference to the string argument

| Int of (int -> unit)

Call the function with an int argument

| Set_int of int Pervasives.ref

Set the reference to the int argument

| Float of (float -> unit)

Call the function with a oat argument

| Set_float of float Pervasives.ref

Set the reference to the oat argument

| Tuple of spec list

Take several arguments according to the spec list

| Symbol of string list * (string -> unit)

Take one of the symbols as argument and call the function with the symbol

| Rest of (string -> unit)

Stop interpreting keywords and call the function with each remaining argument

The concrete type describing the behavior associated with a keyword.

type key = string

type doc = string

type usage_msg = string

type anon_fun = string -> unit

val parse : (key * spec * doc) list -> anon_fun -> usage_msg -> unit

Arg.parse speclist anon_fun usage_msg parses the command line. speclist is a list of triples (key, spec, doc) . key is the option keyword, it must start with a '-' character. spec gives the option type and the function to call when this option is found on the command line. doc is a one-line description of this option. anon_fun is called on anonymous arguments. The functions in spec and anon_fun are called in the same order as their arguments appear on the command line.

If an error occurs, Arg.parse exits the program, after printing to standard error an error message as follows:

- The reason for the error: unknown option, invalid or missing argument, etc.
- usage_msg
- The list of options, each followed by the corresponding doc string.

For the user to be able to specify anonymous arguments starting with a , include for example ("-", String anon_fun, doc) in speclist .

By default, parse recognizes two unit options, -help and help , which will print to standard output usage_msg and the list of options, and exit the program. You can override this behaviour by specifying your own -help and help options in speclist .

val parse_argv :
  ?current:int Pervasives.ref ->
  string array ->
  (key * spec * doc) list -> anon_fun -> usage_msg -> unit

    Arg.parse_argv current args speclist anon_fun usage_msg   parses the array args as
    if it were the command line. It uses and updates the value of current   (if given), or
    Arg.current . You must set it before calling parse_argv . The initial value of current is the
    index of the program name (argument 0) in the array. If an error occurs, Arg.parse_argv
    raises Arg.Bad with the error message as argument. If option -help or help is given,
    Arg.parse_argv raises Arg.Help with the help message as argument.

exception Help of string

    Raised by Arg.parse_argv when the user asks for help.

exception Bad of string

    Functions in spec or anon_fun can raise Arg.Bad with an error message to reject invalid
    arguments. Arg.Bad is also raised by Arg.parse_argv in case of an error.

val usage : (key * spec * doc) list -> usage_msg -> unit

    Arg.usage speclist usage_msg prints to standard error an error message that includes the
    list of valid options. This is the same message that Arg.parse [1] prints in case of error.
    speclist   and usage_msg are the same as for Arg.parse .

val usage_string : (key * spec * doc) list -> usage_msg -> string

    Returns the message that would have been printed by Arg.usage [1], if provided with the
    same parameters.

val align : (key * spec * doc) list -> (key * spec * doc) list

    Align the documentation strings by inserting spaces at the rst space, according to the
    length of the keyword. Use a space as the rst character in a doc string if you want to align
    the whole string. The doc strings corresponding to Symbol arguments are aligned on the
    next line.

val current : int Pervasives.ref

    Position (in Sys.argv [43]) of the argument being processed. You can change this value, e.g.
    to force Arg.parse [1] to skip some arguments. Arg.parse [1] uses the initial value of
    Arg.current [1] as the index of argument 0 (the program name) and starts parsing
    arguments at the next element.

2   Module Array : Array operations.

val length : 'a array -> int

    Return the length (number of elements) of the given array.

val get : 'a array -> int -> 'a

Array.get a n returns the element number n of array a. The first element has number 0. The last element has number Array.length a - 1. You can also write a.(n) instead of Array.get a n.

Raise Invalid_argument "index out of bounds" if n is outside the range 0 to (Array.length a - 1).

val set : 'a array -> int -> 'a -> unit

Array.set a n x modifies array a in place, replacing element number n with x. You can also write a.(n) <- x instead of Array.set a n x.

Raise Invalid_argument "index out of bounds" if n is outside the range 0 to Array.length a - 1.

val make : int -> 'a -> 'a array

Array.make n x returns a fresh array of length n, initialized with x. All the elements of this new array are initially physically equal to x (in the sense of the == predicate). Consequently, if x is mutable, it is shared among all elements of the array, and modifying x through one of the array entries will modify all other entries at the same time.

Raise Invalid_argument if n < 0 or n > Sys.max_array_length. If the value of x is a floating-point number, then the maximum size is only Sys.max_array_length / 2.

val create : int -> 'a -> 'a array

Deprecated. Array.create is an alias for Array.make [2].

val init : int -> (int -> 'a) -> 'a array

Array.init n f returns a fresh array of length n, with element number i initialized to the result of f i. In other terms, Array.init n f tabulates the results of f applied to the integers 0 to n-1.

Raise Invalid_argument if n < 0 or n > Sys.max_array_length. If the return type of f is float, then the maximum size is only Sys.max_array_length / 2.

val make_matrix : int -> int -> 'a -> 'a array array

Array.make_matrix dimx dimy e returns a two-dimensional array (an array of arrays) with first dimension dimx and second dimension dimy. All the elements of this new matrix are initially physically equal to e. The element (x,y) of a matrix m is accessed with the notation m.(x).(y).

Raise Invalid_argument if dimx or dimy is negative or greater than Sys.max_array_length. If the value of e is a floating-point number, then the maximum size is only Sys.max_array_length / 2.

val create_matrix : int -> int -> 'a -> 'a array array

Deprecated. Array.create_matrix is an alias for Array.make_matrix [2].

val append : 'a array -> 'a array -> 'a array

Array.append `v1` `v2` returns a fresh array containing the concatenation of the arrays `v1` and `v2`.

val concat : 'a array list -> 'a array

Same as `Array.append`, but concatenates a list of arrays.

val sub : 'a array -> int -> int -> 'a array

`Array.sub a start len` returns a fresh array of length `len`, containing the elements number `start` to `start + len - 1` of array a.

Raise `Invalid_argument "Array.sub"` if `start` and `len` do not designate a valid subarray of a; that is, if `start < 0`, or `len < 0`, or `start + len > Array.length a`.

val copy : 'a array -> 'a array

`Array.copy a` returns a copy of a, that is, a fresh array containing the same elements as a.

val fill : 'a array -> int -> int -> 'a -> unit

`Array.fill a ofs len x` modies the array a in place, storing `x` in elements number `ofs` to `ofs + len - 1`.

Raise `Invalid_argument "Array.fill"` if `ofs` and `len` do not designate a valid subarray of a.

val blit : 'a array -> int -> 'a array -> int -> int -> unit

`Array.blit v1 o1 v2 o2 len` copies `len` elements from array `v1`, starting at element number `o1`, to array `v2`, starting at element number `o2`. It works correctly even if v1 and v2 are the same array, and the source and destination chunks overlap.

Raise `Invalid_argument "Array.blit"` if `o1` and `len` do not designate a valid subarray of v1, or if `o2` and `len` do not designate a valid subarray of v2.

val to_list : 'a array -> 'a list

`Array.to_list a` returns the list of all the elements of a.

val of_list : 'a list -> 'a array

`Array.of_list l` returns a fresh array containing the elements of l.

val iter : ('a -> unit) -> 'a array -> unit

`Array.iter f a` applies function `f` in turn to all the elements of a. It is equivalent to `f a.(0); f a.(1); ...; f a.(Array.length a - 1); ()`.

val map : ('a -> 'b) -> 'a array -> 'b array

`Array.map f a` applies function `f` to all the elements of a, and builds an array with the results returned by `f`: `[| f a.(0); f a.(1); ...; f a.(Array.length a - 1) |]`.

val iteri : (int -> 'a -> unit) -> 'a array -> unit

Same as Array.iter [2], but the function is applied to the index of the element as first argument, and the element itself as second argument.

val mapi : (int -> 'a -> 'b) -> 'a array -> 'b array

Same as Array.map[2], but the function is applied to the index of the element as first argument, and the element itself as second argument.

val fold_left : ('a -> 'b -> 'a) -> 'a -> 'b array -> 'a

Array.fold_left f x a computes f (... (f (f x a.(0)) a.(1)) ...) a.(n-1), where n is the length of the array a.

val fold_right : ('a -> 'b -> 'b) -> 'a array -> 'b -> 'b

Array.fold_right f a x computes f a.(0) (f a.(1) (... (f a.(n-1) x) ...)), where n is the length of the array a.

Sorting

val sort : ('a -> 'a -> int) -> 'a array -> unit

Sort an array in increasing order according to a comparison function. The comparison function must return 0 if its arguments compare as equal, a positive integer if the first is greater, and a negative integer if the first is smaller (see below for a complete specification). For example, Pervasives.compare [30] is a suitable comparison function, provided there are no floating-point NaN values in the data. After calling Array.sort, the array is sorted in place in increasing order. Array.sort is guaranteed to run in constant heap space and (at most) logarithmic stack space.

The current implementation uses Heap Sort. It runs in constant stack space.

Specification of the comparison function: Let a be the array and cmp the comparison function. The following must be true for all x, y, z in a :

- cmp x y > 0 if and only if cmp y x < 0
- if cmp x y ≥ 0 and cmp y z ≥ 0 then cmp x z ≥ 0

When Array.sort returns, a contains the same elements as before, reordered in such a way that for all i and j valid indices of a :

- cmp a.(i) a.(j) ≥ 0 if and only if i ≥ j

val stable_sort : ('a -> 'a -> int) -> 'a array -> unit

Same as Array.sort [2], but the sorting algorithm is stable (i.e. elements that compare equal are kept in their original order) and not guaranteed to run in constant heap space.

The current implementation uses Merge Sort. It uses $n/2$ words of heap space, where n is the length of the array. It is usually faster than the current implementation of Array.sort [2].

val fast_sort : ('a -> 'a -> int) -> 'a array -> unit

Same as Array.sort [2] or Array.stable_sort [2], whichever is faster on typical input.

3 Module ArrayLabels : Array operations.

val length : 'a array -> int

> Return the length (number of elements) of the given array.

val get : 'a array -> int -> 'a

> Array.get a n returns the element number n of array a. The rst element has number 0. The last element has number Array.length a - 1 . You can also write a.(n) instead of Array.get a n .

> Raise Invalid_argument "index out of bounds" if n is outside the range 0 to (Array.length a - 1) .

val set : 'a array -> int -> 'a -> unit

> Array.set a n x modi es array a in place, replacing element number n with x. You can also write a.(n) <- x instead of Array.set a n x .

> Raise Invalid_argument "index out of bounds" if n is outside the range 0 to Array.length a - 1 .

val make : int -> 'a -> 'a array

> Array.make n x returns a fresh array of length n, initialized with x. All the elements of this new array are initially physically equal to x (in the sense of the == predicate). Consequently, if x is mutable, it is shared among all elements of the array, and modifying x through one of the array entries will modify all other entries at the same time.

> Raise Invalid_argument if n < 0 or n > Sys.max_array_length . If the value of x is a oating-point number, then the maximum size is only Sys.max_array_length / 2 .

val create : int -> 'a -> 'a array

> Deprecated. Array.create is an alias for ArrayLabels.make [3].

val init : int -> f:(int -> 'a) -> 'a array

> Array.init n f returns a fresh array of length n, with element number i initialized to the result of f i . In other terms, Array.init n f tabulates the results of f applied to the integers 0 to n-1 .

> Raise Invalid_argument if n < 0 or n > Sys.max_array_length . If the return type of f is float , then the maximum size is only Sys.max_array_length / 2 .

val make_matrix : dimx:int -> dimy:int -> 'a -> 'a array array

> Array.make_matrix dimx dimy e returns a two-dimensional array (an array of arrays) with rst dimension dimx and second dimension dimy. All the elements of this new matrix are initially physically equal to e. The element (x,y) of a matrix m is accessed with the notation m.(x).(y) .

> Raise Invalid_argument if dimx or dimy is negative or greater than Sys.max_array_length . If the value of e is a oating-point number, then the maximum size is only Sys.max_array_length / 2 .

val create_matrix : dimx:int -> dimy:int -> 'a -> 'a array array

    Deprecated. Array.create_matrix is an alias for ArrayLabels.make_matrix [3].

val append : 'a array -> 'a array -> 'a array

    Array.append v1 v2 returns a fresh array containing the concatenation of the arrays v1 and v2.

val concat : 'a array list -> 'a array

    Same as Array.append , but concatenates a list of arrays.

val sub : 'a array -> pos:int -> len:int -> 'a array

    Array.sub a start len returns a fresh array of length len , containing the elements number start to start + len - 1 of array a.

    Raise Invalid_argument "Array.sub" if start and len do not designate a valid subarray of a; that is, if start < 0 , or len < 0, or start + len > Array.length a .

val copy : 'a array -> 'a array

    Array.copy a returns a copy of a, that is, a fresh array containing the same elements as a.

val fill : 'a array -> pos:int -> len:int -> 'a -> unit

    Array.fill a ofs len x modi es the array a in place, storing x in elements number ofs to ofs + len - 1 .

    Raise Invalid_argument "Array.fill" if ofs and len do not designate a valid subarray of a.

val blit :
  src:'a array -> src_pos:int -> dst:'a array -> dst_pos:int -> len:int -> unit

    Array.blit v1 o1 v2 o2 len copies len elements from array v1, starting at element number o1, to array v2, starting at element number o2. It works correctly even if v1 and v2 are the same array, and the source and destination chunks overlap.

    Raise Invalid_argument "Array.blit" if o1 and len do not designate a valid subarray of v1, or if o2 and len do not designate a valid subarray of v2.

val to_list : 'a array -> 'a list

    Array.to_list a returns the list of all the elements of a.

val of_list : 'a list -> 'a array

    Array.of_list l returns a fresh array containing the elements of l .

val iter : f:('a -> unit) -> 'a array -> unit

    Array.iter f a applies function f in turn to all the elements of a. It is equivalent to f a.(0); f a.(1); ...; f a.(Array.length a - 1); () .

val map : f:('a -> 'b) -> 'a array -> 'b array

Array.map f a applies function f to all the elements of a, and builds an array with the results returned by f : [| f a.(0); f a.(1); ...; f a.(Array.length a - 1) |] .

val iteri : f:(int -> 'a -> unit) -> 'a array -> unit

Same as ArrayLabels.iter [3], but the function is applied to the index of the element as rst argument, and the element itself as second argument.

val mapi : f:(int -> 'a -> 'b) -> 'a array -> 'b array

Same as ArrayLabels.map [3], but the function is applied to the index of the element as rst argument, and the element itself as second argument.

val fold_left : f:('a -> 'b -> 'a) -> init:'a -> 'b array -> 'a

Array.fold_left f x a computes f (... (f (f x a.(0)) a.(1)) ...) a.(n-1) , where n is the length of the array a.

val fold_right : f:('a -> 'b -> 'b) -> 'a array -> init:'b -> 'b

Array.fold_right f a x computes f a.(0) (f a.(1) (... (f a.(n-1) x) ...)) , where n is the length of the array a.

Sorting

val sort : cmp:('a -> 'a -> int) -> 'a array -> unit

Sort an array in increasing order according to a comparison function. The comparison function must return 0 if its arguments compare as equal, a positive integer if the rst is greater, and a negative integer if the rst is smaller (see below for a complete speci cation). For example, Pervasives.compare [30] is a suitable comparison function, provided there are no oating-point NaN values in the data. After calling Array.sort , the array is sorted in place in increasing order. Array.sort is guaranteed to run in constant heap space and (at most) logarithmic stack space.

The current implementation uses Heap Sort. It runs in constant stack space.

Speci cation of the comparison function: Let a be the array and cmp the comparison function. The following must be true for all x, y, z in a :

- cmp x y $>$ 0 if and only if cmp y x $<$ 0
- if cmp x y $\geq$ 0 and cmp y z $\geq$ 0 then cmp x z $\geq$ 0

When Array.sort returns, a contains the same elements as before, reordered in such a way that for all i and j valid indices of a :

- cmp a.(i) a.(j) $\geq$ 0 if and only if i $\geq$ j

val stable_sort : cmp:('a -> 'a -> int) -> 'a array -> unit

Same as ArrayLabels.sort [3], but the sorting algorithm is stable (i.e. elements that compare equal are kept in their original order) and not guaranteed to run in constant heap space.

The current implementation uses Merge Sort. It uses $n/2$ words of heap space, where n is the length of the array. It is usually faster than the current implementation of ArrayLabels.sort [3].

val fast_sort : cmp:('a -> 'a -> int) -> 'a array -> unit

Same as Array.sort [2] or Array.stable_sort [2], whichever is faster on typical input.

4   Module Buffer : Extensible string buffers.

This module implements string buffers that automatically expand as necessary. It provides accumulative concatenation of strings in quasi-linear time (instead of quadratic time when strings are concatenated pairwise).

type t

The abstract type of buffers.

val create : int -> t

create n returns a fresh buffer, initially empty. The n parameter is the initial size of the internal string that holds the buffer contents. That string is automatically reallocated when more than n characters are stored in the buffer, but shrinks back to n characters when reset is called. For best performance, n should be of the same order of magnitude as the number of characters that are expected to be stored in the buffer (for instance, 80 for a buffer that holds one output line). Nothing bad will happen if the buffer grows beyond that limit, however. In doubt, take n = 16 for instance. If n is not between 1 and Sys.max_string_length [43], it will be clipped to that interval.

val contents : t -> string

Return a copy of the current contents of the buffer. The buffer itself is unchanged.

val sub : t -> int -> int -> string

Buffer.sub b off len returns (a copy of) the substring of the current contents of the buffer b starting at offset off of length len bytes. May raise Invalid_argument if out of bounds request. The buffer itself is unaffected.

val blit : t -> int -> string -> int -> int -> unit

Buffer.blit src srcoff dst dstoff len copies len characters from the current contents of the buffer src, starting at offset srcoff to string dst, starting at character dstoff.

Raise Invalid_argument if srcoff and len do not designate a valid substring of src, or if dstoff and len do not designate a valid substring of dst.

Since: 3.11.2

val nth : t -> int -> char

get the n-th character of the buffer. Raise Invalid_argument if index out of bounds

val length : t -> int

    Return the number of characters currently contained in the buer.

val clear : t -> unit

    Empty the buer.

val reset : t -> unit

    Empty the buer and deallocate the internal string holding the buer contents, replacing it with the initial internal string of length n that was allocated by Buffer.create [4] n. For long-lived buers that may have grown a lot, reset allows faster reclamation of the space used by the buer.

val add_char : t -> char -> unit

    add_char b c appends the character c at the end of the buer b.

val add_string : t -> string -> unit

    add_string b s appends the string s at the end of the buer b.

val add_substring : t -> string -> int -> int -> unit

    add_substring b s ofs len takes len characters from oset ofs in string s and appends them at the end of the buer b.

val add_substitute : t -> (string -> string) -> string -> unit

    add_substitute b f s appends the string pattern s at the end of the buer b with substitution. The substitution process looks for variables into the pattern and substitutes each variable name by its value, as obtained by applying the mapping f to the variable name. Inside the string pattern, a variable name immediately follows a non-escaped $ character and is one of the following:

        ● a non empty sequence of alphanumeric or _ characters,
        ● an arbitrary sequence of characters enclosed by a pair of matching parentheses or curly brackets. An escaped $ character is a $ that immediately follows a backslash character; it then stands for a plain $. Raise Not_found if the closing character of a parenthesized variable cannot be found.

val add_buffer : t -> t -> unit

    add_buffer b1 b2 appends the current contents of buer b2 at the end of buer b1. b2 is not modied.

val add_channel : t -> Pervasives.in_channel -> int -> unit

    add_channel b ic n reads exactly n character from the input channel ic and stores them at the end of buer b. Raise End_of_file if the channel contains fewer than n characters.

val output_buffer : Pervasives.out_channel -> t -> unit

    output_buffer oc b writes the current contents of buer b on the output channel oc.

13

5 Module Callback : Registering Caml values with the C runtime.

This module allows Caml values to be registered with the C runtime under a symbolic name, so that C code can later call back registered Caml functions, or raise registered Caml exceptions.

val register : string -> 'a -> unit

> Callback.register n v   registers the valuev under the namen. C code can later retrieve a handle to v by calling caml_named_value(n).

val register_exception : string -> exn -> unit

> Callback.register_exception n exn   registers the exception contained in the exception value exn under the namen. C code can later retrieve a handle to the exception by calling caml_named_value(n). The exception value thus obtained is suitable for passign as rst argument to raise_constant or raise_with_arg .

6 Module CamlinternalLazy

exception Undefined
val force_lazy_block : 'a lazy_t -> 'a
val force_val_lazy_block : 'a lazy_t -> 'a
val force : 'a lazy_t -> 'a
val force_val : 'a lazy_t -> 'a

7 Module CamlinternalMod

```
type shape =
  | Function
  | Lazy
  | Class
  | Module of shape array
val init_mod : string * int * int -> shape -> Obj.t
val update_mod : shape -> Obj.t -> Obj.t -> unit
```

8 Module CamlinternalOO : Run-time support for objects and classes.

All functions in this module are for system use only, not for the casual user.

  methods : int ;
  inst_vars : int ;
}
val stats : unit -> stats
```

9   Module Char : Character operations.

val code : char -> int

>   Return the ASCII code of the argument.

val chr : int -> char

>   Return the character with the given ASCII code. RaiseInvalid_argument "Char.chr"   if
>   the argument is outside the range 0 255.

val escaped : char -> string

>   Return a string representing the given character, with special characters escaped following
>   the lexical conventions of Objective Caml.

val lowercase : char -> char

>   Convert the given character to its equivalent lowercase character.

val uppercase : char -> char

>   Convert the given character to its equivalent uppercase character.

type t = char

An alias for the type of characters.

val compare : t -> t -> int

The comparison function for characters, with the same speci cation as
Pervasives.compare [30]. Along with the type t , this function compare allows the module
Char to be passed as argument to the functors Set.Make [36] and Map.Make [23].

10   Module Complex: Complex numbers.

This module provides arithmetic operations on complex numbers. Complex numbers are represented
by their real and imaginary parts (cartesian representation). Each part is represented by a double-
precision oating-point number (type float).

```
type t = {
  re : float ;
  im : float ;
}
```

The type of complex numbers. re is the real part and im the imaginary part.

val zero : t

The complex number 0.

val one : t

The complex number 1.

val i : t

The complex number i .

val neg : t -> t

Unary negation.

val conj : t -> t

Conjugate: given the complex x + i.y , returns x - i.y .

val add : t -> t -> t

Addition

val sub : t -> t -> t

Subtraction

val mul : t -> t -> t

Multiplication

val inv : t -> t

Multiplicative inverse (1/z).

val div : t -> t -> t
    Division

val sqrt : t -> t
    Square root. The result x + i.y is such that x > 0 or x = 0 and y >= 0. This function has
    a discontinuity along the negative real axis.

val norm2 : t -> float
    Norm squared: given x + i.y , returns x^2 + y^2.

val norm : t -> float
    Norm: given x + i.y , returns sqrt(x^2 + y^2) .

val arg : t -> float
    Argument. The argument of a complex number is the angle in the complex plane between
    the positive real axis and a line passing through zero and the number. This angle ranges
    from -pi to pi . This function has a discontinuity along the negative real axis.

val polar : float -> float -> t
    polar norm arg returns the complex having norm norm and argument arg .

val exp : t -> t
    Exponentiation. exp z returns e to the z power.

val log : t -> t
    Natural logarithm (in base e).

val pow : t -> t -> t
    Power function. pow z1 z2 returns z1 to the z2 power.

11   Module Digest : MD5 message digest.

This module provides functions to compute 128-bit digests of arbitrary-length strings or les. The
digests are of cryptographic quality: it is very hard, given a digest, to forge a string having that
digest. The algorithm used is MD5.

type t = string
    The type of digests: 16-character strings.

val string : string -> t
    Return the digest of the given string.

val substring : string -> int -> int -> t

    Digest.substring s ofs len   returns the digest of the substring ofs starting at character number ofs and containing len characters.

val channel : Pervasives.in_channel -> int -> t

    If len is nonnegative, Digest.channel ic len   reads len characters from channel ic and returns their digest, or raises End_of_file if end-of- le is reached before len characters are read. If len is negative, Digest.channel ic len   reads all characters from ic until end-of- le is reached and return their digest.

val file : string -> t

    Return the digest of the le whose name is given.

val output : Pervasives.out_channel -> t -> unit

    Write a digest on the given output channel.

val input : Pervasives.in_channel -> t

    Read a digest from the given input channel.

val to_hex : t -> string

    Return the printable hexadecimal representation of the given digest.

12   Module Filename : Operations on le names.

val current_dir_name : string

    The conventional name for the current directory (e.g. . in Unix).

val parent_dir_name : string

    The conventional name for the parent of the current directory (e.g... in Unix).

val dir_sep : string

    The directory separator (e.g. / in Unix).

    Since: 3.11.2

val concat : string -> string -> string

    concat dir file   returns a le name that designates le file in directory dir .

val is_relative : string -> bool

    Return true if the le name is relative to the current directory, false if it is absolute (i.e. in Unix, starts with /).

val is_implicit : string -> bool

Return true if the file name is relative and does not start with an explicit reference to the current directory (./ or ../ in Unix), false if it starts with an explicit reference to the root directory or the current directory.

val check_suffix : string -> string -> bool

check_suffix name suff returns true if the filename name ends with the suffix suff.

val chop_suffix : string -> string -> string

chop_suffix name suff removes the suffix suff from the filename name. The behavior is undefined if name does not end with the suffix suff.

val chop_extension : string -> string

Return the given file name without its extension. The extension is the shortest suffix starting with a period and not including a directory separator, .xyz for instance.

Raise Invalid_argument if the given name does not contain an extension.

val basename : string -> string

Split a file name into directory name / base file name. concat (dirname name) (basename name) returns a file name which is equivalent to name. Moreover, after setting the current directory to dirname name (with Sys.chdir [43]), references to basename name (which is a relative file name) designate the same file as name before the call to Sys.chdir [43].

The result is not specified if the argument is not a valid file name (for example, under Unix if there is a NUL character in the string).

val dirname : string -> string

See Filename.basename [12].

val temp_file : ?temp_dir:string -> string -> string -> string

temp_file prefix suffix returns the name of a fresh temporary file in the temporary directory. The base name of the temporary file is formed by concatenating prefix, then a suitably chosen integer number, then suffix. The optional argument temp_dir indicates the temporary directory to use, defaulting to Filename.temp_dir_name [12]. The temporary file is created empty, with permissions 0o600 (readable and writable only by the file owner). The file is guaranteed to be different from any other file that existed when temp_file was called. Raise Sys_error if the file could not be created.

Before 3.11.2 no ?temp_dir optional argument

val open_temp_file :
  ?mode:Pervasives.open_flag list ->
  ?temp_dir:string -> string -> string -> string * Pervasives.out_channel

Same as Filename.temp_file [12], but returns both the name of a fresh temporary file, and an output channel opened (atomically) on this file. This function is more secure than temp_file : there is no risk that the temporary file will be modified (e.g. replaced by a symbolic link) before the program opens it. The optional argument mode is a list of

21

additional ags to control the opening of the le. It can contain one or several of
Open_append, Open_binary, and Open_text. The default is [Open_text] (open in text
mode). Raise Sys_error if the le could not be opened.

Before 3.11.2 no ?temp_dir optional argument

val temp_dir_name : string

The name of the temporary directory: Under Unix, the value of the TMPDIR environment
variable, or "/tmp" if the variable is not set. Under Windows, the value of the TEMP
environment variable, or "." if the variable is not set.

Since: 3.09.1

val quote : string -> string

Return a quoted version of a le name, suitable for use as one argument in a command line,
escaping all meta-characters. Warning: under Windows, the output is only suitable for use
with programs that follow the standard Windows quoting conventions.

13 Module Format : Pretty printing.

This module implements a pretty-printing facility to format text within pretty-printing boxes . The
pretty-printer breaks lines at speci ed break hints, and indents lines according to the box structure.

For a gentle introduction to the basics of pretty-printing using Format, read http://caml.inria.fr/resources/doc
//caml.inria.fr/resources/doc/guides/format.html].

You may consider this module as providing an extension to the printf facility to provide au-
tomatic line breaking. The addition of pretty-printing annotations to your regular printf formats
gives you fancy indentation and line breaks. Pretty-printing annotations are described below in the
documentation of the function Format.fprintf [13].

You may also use the explicit box management and printing functions provided by this module.
This style is more basic but more verbose than the fprintf concise formats.

For instance, the sequence open_box 0; print_string "x ="; print_space (); print_int
1; close_box (); print_newline () that prints x = 1 within a pretty-printing box, can be ab-
breviated as printf "@[%s@ %i@]@." "x =" 1, or even shorter printf "@[x =@ %i@]@." 1.

Rule of thumb for casual users of this library:

- use simple boxes (as obtained by open_box 0);

- use simple break hints (as obtained by print_cut () that outputs a simple break hint, or by
  print_space () that outputs a space indicating a break hint);

- once a box is opened, display its material with basic printing functions (e. g. print_int and
  print_string);

- when the material for a box has been printed, call close_box () to close the box;

- at the end of your routine, ush the pretty-printer to display all the remaining material, e.g.
  evaluate print_newline () .

The behaviour of pretty-printing commands is unspecied if there is no opened pretty-printing box. Each box opened via one of the open_ functions below must be closed using close_box for proper formatting. Otherwise, some of the material printed in the boxes may not be output, or may be formatted incorrectly.

In case of interactive use, the system closes all opened boxes and ushes all pending text (as with the print_newline function) after each phrase. Each phrase is therefore executed in the initial state of the pretty-printer.

Warning: the material output by the following functions is delayed in the pretty-printer queue in order to compute the proper line breaking. Hence, you should not mix calls to the printing functions of the basic I/O system with calls to the functions of this module: this could result in some strange output seemingly unrelated with the evaluation order of printing commands.

Boxes

val open_box : int -> unit

open_box d opens a new pretty-printing box with oset d. This box is the general purpose pretty-printing box. Material in this box is displayed horizontal or vertical : break hints inside the box may lead to a new line, if there is no more room on the line to print the remainder of the box, or if a new line may lead to a new indentation (demonstrating the indentation of the box). When a new line is printed in the box, d is added to the current indentation.

val close_box : unit -> unit

Closes the most recently opened pretty-printing box.

Formatting functions

val print_string : string -> unit

print_string str prints str in the current box.

val print_as : int -> string -> unit

print_as len str prints str in the current box. The pretty-printer formats str as if it were of length len .

val print_int : int -> unit

Prints an integer in the current box.

val print_float : float -> unit

Prints a oating point number in the current box.

val print_char : char -> unit

Prints a character in the current box.

val print_bool : bool -> unit

Prints a boolean in the current box.

Break hints

val print_space : unit -> unit

print_space ()   is used to separate items (typically to print a space between two words). It indicates that the line may be split at this point. It either prints one space or splits the line. It is equivalent to print_break 1 0 .

val print_cut : unit -> unit

print_cut ()   is used to mark a good break position. It indicates that the line may be split at this point. It either prints nothing or splits the line. This allows line splitting at the current point, without printing spaces or adding indentation. It is equivalent to print_break 0 0 .

val print_break : int -> int -> unit

Inserts a break hint in a pretty-printing box. print_break nspaces offset   indicates that the line may be split (a newline character is printed) at this point, if the contents of the current box does not t on the current line. If the line is split at that point, offset   is added to the current indentation. If the line is not split, nspaces spaces are printed.

val print_flush : unit -> unit

Flushes the pretty printer: all opened boxes are closed, and all pending text is displayed.

val print_newline : unit -> unit

Equivalent to print_flush   followed by a new line.

val force_newline : unit -> unit

Forces a newline in the current box. Not the normal way of pretty-printing, you should prefer break hints.

val print_if_newline : unit -> unit

Executes the next formatting command if the preceding line has just been split. Otherwise, ignore the next formatting command.

Margin

val set_margin : int -> unit

set_margin d sets the value of the right margin to d (in characters): this value is used to detect line over ows that leads to split lines. Nothing happens if d is smaller than 2. If d is too large, the right margin is set to the maximum admissible value (which is greater than 10^10).

val get_margin : unit -> int

Returns the position of the right margin.

Maximum indentation limit

val set_max_indent : int -> unit

set_max_indent d sets the value of the maximum indentation limit to d (in characters): once this limit is reached, boxes are rejected to the left, if they do not t on the current line. Nothing happens if d is smaller than 2. If d is too large, the limit is set to the maximum admissible value (which is greater than 10^10).

24

val get_max_indent : unit -> int

    Return the value of the maximum indentation limit (in characters).

   Formatting depth: maximum number of boxes allowed before ellipsis

val set_max_boxes : int -> unit

    set_max_boxes max sets the maximum number of boxes simultaneously opened. Material inside boxes nested deeper is printed as an ellipsis (more precisely as the text returned by get_ellipsis_text ()). Nothing happens if max is smaller than 2.

val get_max_boxes : unit -> int

    Returns the maximum number of boxes allowed before ellipsis.

val over_max_boxes : unit -> bool

    Tests if the maximum number of boxes allowed have already been opened.

   Advanced formatting

val open_hbox : unit -> unit

    open_hbox () opens a new pretty-printing box. This box is horizontal : the line is not split in this box (new lines may still occur inside boxes nested deeper).

val open_vbox : int -> unit

    open_vbox d opens a new pretty-printing box with o set d. This box is vertical : every break hint inside this box leads to a new line. When a new line is printed in the box, d is added to the current indentation.

val open_hvbox : int -> unit

    open_hvbox d opens a new pretty-printing box with o set d. This box is horizontal-vertical : it behaves as an horizontal box if it ts on a single line, otherwise it behaves as a vertical box. When a new line is printed in the box, d is added to the current indentation.

val open_hovbox : int -> unit

    open_hovbox d opens a new pretty-printing box with o set d. This box is horizontal or vertical : break hints inside this box may lead to a new line, if there is no more room on the line to print the remainder of the box. When a new line is printed in the box, d is added to the current indentation.

   Tabulations

val open_tbox : unit -> unit

    Opens a tabulation box.

val close_tbox : unit -> unit

    Closes the most recently opened tabulation box.

val print_tbreak : int -> int -> unit

Break hint in a tabulation box. print_tbreak spaces offset moves the insertion point to the next tabulation (spaces being added to this position). Nothing occurs if insertion point is already on a tabulation mark. If there is no next tabulation on the line, then a newline is printed and the insertion point moves to the rst tabulation of the box. If a new line is printed, offset is added to the current indentation.

val set_tab : unit -> unit

Sets a tabulation mark at the current insertion point.

val print_tab : unit -> unit

print_tab () is equivalent to print_tbreak 0 0 .

Ellipsis

val set_ellipsis_text : string -> unit

Set the text of the ellipsis printed when too many boxes are opened (a single dot, by default).

val get_ellipsis_text : unit -> string

Return the text of the ellipsis.

Semantics Tags

type tag = string

Semantics tags (or simply tags) are used to decorate printed entities for user's de ned purposes, e.g. setting font and giving size indications for a display device, or marking delimitation of semantics entities (e.g. HTML or TeX elements or terminal escape sequences).

By default, those tags do not in uence line breaking calculation: the tag markers are not considered as part of the printing material that drives line breaking (in other words, the length of those strings is considered as zero for line breaking).

Thus, tag handling is in some sense transparent to pretty-printing and does not interfere with usual pretty-printing. Hence, a single pretty printing routine can output both simple verbatim material or richer decorated output depending on the treatment of tags. By default, tags are not active, hence the output is not decorated with tag information. Once set_tags is set to true , the pretty printer engine honours tags and decorates the output accordingly.

When a tag has been opened (or closed), it is both and successively printed and marked . Printing a tag means calling a formatter speci c function with the name of the tag as argument: that tag printing function can then print any regular material to the formatter (so that this material is enqueued as usual in the formatter queue for further line-breaking computation). Marking a tag means to output an arbitrary string (the tag marker), directly into the output device of the formatter. Hence, the formatter speci c tag marking function must return the tag marker string associated to its tag argument. Being ushed directly into the output device of the formatter, tag marker strings are not considered as part of the printing material that drives line breaking (in other words, the length of the strings corresponding to tag markers is considered as zero for line breaking). In addition, advanced users may take advantage of the speci city of tag markers to be precisely output when the pretty printer has already decided where to break the lines, and precisely when the queue is ushed into the output device.

In the spirit of HTML tags, the default tag marking functions output tags enclosed in "$<$" and "$>$": hence, the opening marker of tag t is "<t>" and the closing marker "</t>" .

Default tag printing functions just do nothing.

Tag marking and tag printing functions are user definable and can be set by calling set_formatter_tag_functio

val open_tag : tag -> unit

> open_tag t opens the tag named t ; the print_open_tag   function of the formatter is called with t as argument; the tag marker mark_open_tag t will be flushed into the output device of the formatter.

val close_tag : unit -> unit

> close_tag ()   closes the most recently opened tag. In addition, the print_close_tag function of the formatter is called with t as argument. The marker mark_close_tag t will be flushed into the output device of the formatter.

val set_tags : bool -> unit

> set_tags b turns on or off the treatment of tags (default is off).

val set_print_tags : bool -> unit

val set_mark_tags : bool -> unit

> set_print_tags b   turns on or off the printing of tags, while set_mark_tags b turns on or off the output of tag markers.

val get_print_tags : unit -> bool

val get_mark_tags : unit -> bool

> Return the current status of tags printing and tags marking.

Redirecting the standard formatter output

val set_formatter_out_channel : Pervasives.out_channel -> unit

> Redirect the pretty-printer output to the given channel. (All the output functions of the standard formatter are set to the default output functions printing to the given channel.)

val set_formatter_output_functions :

  (string -> int -> int -> unit) -> (unit -> unit) -> unit

> set_formatter_output_functions out flush   redirects the relevant pretty-printer output functions to the functions out and flush .

> The out function performs the pretty-printer string output. It is called with a string s, a start position p, and a number of characters n; it is supposed to output characters p to p + n - 1 of s. The flush   function is called whenever the pretty-printer is flushed (via conversion %!, pretty-printing indications @? or @, or using low level function print_flush or print_newline   ).

val get_formatter_output_functions :

  unit -> (string -> int -> int -> unit) * (unit -> unit)

> Return the current output functions of the pretty-printer.

27

Changing the meaning of standard formatter pretty printing

The Format module is versatile enough to let you completely rede ne the meaning of pretty printing: you may provide your own functions to de ne how to handle indentation, line breaking, and even printing of all the characters that have to be printed!

val set_all_formatter_output_functions :
  out:(string -> int -> int -> unit) ->
  flush:(unit -> unit) ->
  newline:(unit -> unit) -> spaces:(int -> unit) -> unit

> set_all_formatter_output_functions out flush outnewline outspace   redirects the pretty-printer output to the functions out and flush as described in set_formatter_output_functions . In addition, the pretty-printer function that outputs a newline is set to the function outnewline and the function that outputs indentation spaces is set to the function outspace .

> This way, you can change the meaning of indentation (which can be something else than just printing space characters) and the meaning of new lines opening (which can be connected to any other action needed by the application at hand). The two functions outspace and outnewline are normally connected to out and flush : respective default values for outspace and outnewline are out (String.make n ' ') 0 n and out "\n" 0 1 .

val get_all_formatter_output_functions :
  unit ->
  (string -> int -> int -> unit) * (unit -> unit) * (unit -> unit) *
  (int -> unit)

> Return the current output functions of the pretty-printer, including line breaking and indentation functions. Useful to record the current setting and restore it afterwards.

Changing the meaning of printing semantics tags

type formatter_tag_functions = {
  mark_open_tag : tag -> string ;
  mark_close_tag : tag -> string ;
  print_open_tag : tag -> unit ;
  print_close_tag : tag -> unit ;
}

> The tag handling functions speci c to a formatter: mark versions are the tag marking functions that associate a string marker to a tag in order for the pretty-printing engine to ush those markers as 0 length tokens in the output device of the formatter. print versions are the tag printing functions that can perform regular printing when a tag is closed or opened.

val set_formatter_tag_functions : formatter_tag_functions -> unit

set_formatter_tag_functions tag_funs changes the meaning of opening and closing tags to use the functions in tag_funs .

When opening a tag name t , the string t is passed to the opening tag marking function (the mark_open_tag eld of the record tag_funs), that must return the opening tag marker for that name. When the next call to close_tag () happens, the tag name t is sent back to the closing tag

marking function (the mark_close_tag eld of record tag_funs), that must return a closing tag marker for that name.

The print_ eld of the record contains the functions that are called at tag opening and tag closing time, to output regular material in the pretty-printer queue.

val get_formatter_tag_functions : unit -> formatter_tag_functions

Return the current tag functions of the pretty-printer.

Multiple formatted output

type formatter

Abstract data corresponding to a pretty-printer (also called a formatter) and all its machinery.

De ning new pretty-printers permits unrelated output of material in parallel on several output channels. All the parameters of a pretty-printer are local to this pretty-printer: margin, maximum indentation limit, maximum number of boxes simultaneously opened, ellipsis, and so on, are speci c to each pretty-printer and may be xed independently. Given a Pervasives.out_channel output channel oc, a new formatter writing to that channel is simply obtained by calling formatter_of_out_channel oc . Alternatively, the make_formatter function allocates a new formatter with explicit output and ushing functions (convenient to output material to strings for instance).

val formatter_of_out_channel : Pervasives.out_channel -> formatter

formatter_of_out_channel oc returns a new formatter that writes to the corresponding channel oc.

val std_formatter : formatter

The standard formatter used by the formatting functions above. It is de ned as formatter_of_out_channel stdout .

val err_formatter : formatter

A formatter to use with formatting functions below for output to standard error. It is de ned as formatter_of_out_channel stderr .

val formatter_of_buffer : Buffer.t -> formatter

formatter_of_buffer b returns a new formatter writing to bu er b. As usual, the formatter has to be ushed at the end of pretty printing, using pp_print_flush or pp_print_newline , to display all the pending material.

val stdbuf : Buffer.t

The string bu er in which str_formatter writes.

val str_formatter : formatter

A formatter to use with formatting functions below for output to the stdbuf string bu er. str_formatter is de ned as formatter_of_buffer stdbuf .

val flush_str_formatter : unit -> string

Returns the material printed with str_formatter , ushes the formatter and resets the corresponding bu er.

val make_formatter :
   (string -> int -> int -> unit) -> (unit -> unit) -> formatter

   make_formatter out flush returns a new formatter that writes according to the output function out, and the ushing function flush . For instance, a formatter to the Pervasives.out_channel oc is returned by make_formatter (Pervasives.output oc) (fun () -> Pervasives.flush oc) .

   Basic functions to use with formatters

val pp_open_hbox : formatter -> unit -> unit

val pp_open_vbox : formatter -> int -> unit

val pp_open_hvbox : formatter -> int -> unit

val pp_open_hovbox : formatter -> int -> unit

val pp_open_box : formatter -> int -> unit

val pp_close_box : formatter -> unit -> unit

val pp_open_tag : formatter -> string -> unit

val pp_close_tag : formatter -> unit -> unit

val pp_print_string : formatter -> string -> unit

val pp_print_as : formatter -> int -> string -> unit

val pp_print_int : formatter -> int -> unit

val pp_print_float : formatter -> float -> unit

val pp_print_char : formatter -> char -> unit

val pp_print_bool : formatter -> bool -> unit

val pp_print_break : formatter -> int -> int -> unit

val pp_print_cut : formatter -> unit -> unit

val pp_print_space : formatter -> unit -> unit

val pp_force_newline : formatter -> unit -> unit

val pp_print_flush : formatter -> unit -> unit

val pp_print_newline : formatter -> unit -> unit

val pp_print_if_newline : formatter -> unit -> unit

val pp_open_tbox : formatter -> unit -> unit

val pp_close_tbox : formatter -> unit -> unit

val pp_print_tbreak : formatter -> int -> int -> unit

val pp_set_tab : formatter -> unit -> unit

val pp_print_tab : formatter -> unit -> unit

val pp_set_tags : formatter -> bool -> unit

val pp_set_print_tags : formatter -> bool -> unit

val pp_set_mark_tags : formatter -> bool -> unit

val pp_get_print_tags : formatter -> unit -> bool

val pp_get_mark_tags : formatter -> unit -> bool

val pp_set_margin : formatter -> int -> unit

val pp_get_margin : formatter -> unit -> int

val pp_set_max_indent : formatter -> int -> unit

val pp_get_max_indent : formatter -> unit -> int

val pp_set_max_boxes : formatter -> int -> unit

val pp_get_max_boxes : formatter -> unit -> int

val pp_over_max_boxes : formatter -> unit -> bool

val pp_set_ellipsis_text : formatter -> string -> unit

val pp_get_ellipsis_text : formatter -> unit -> string

val pp_set_formatter_out_channel :
  formatter -> Pervasives.out_channel -> unit

val pp_set_formatter_output_functions :
  formatter -> (string -> int -> int -> unit) -> (unit -> unit) -> unit

val pp_get_formatter_output_functions :
  formatter -> unit -> (string -> int -> int -> unit) * (unit -> unit)

val pp_set_all_formatter_output_functions :
  formatter ->
  out:(string -> int -> int -> unit) ->
  flush:(unit -> unit) ->
  newline:(unit -> unit) -> spaces:(int -> unit) -> unit

val pp_get_all_formatter_output_functions :
  formatter ->
  unit ->
  (string -> int -> int -> unit) * (unit -> unit) * (unit -> unit) *
  (int -> unit)

val pp_set_formatter_tag_functions :
  formatter -> formatter_tag_functions -> unit

val pp_get_formatter_tag_functions :
  formatter -> unit -> formatter_tag_functions

> These functions are the basic ones: usual functions operating on the standard formatter are
> de ned via partial evaluation of these primitives. For instance, print_string is equal to
> pp_print_string std_formatter .

> printf like functions for pretty-printing.

val fprintf : formatter -> ('a, formatter, unit) Pervasives.format -> 'a

> fprintf ff fmt arg1 ... argN formats the argumentsarg1 to argN according to the format
string fmt , and outputs the resulting string on the formatter ff .

> The format fmt is a character string which contains three types of objects: plain characters and
conversion speci cations as speci ed in thePrintf module, and pretty-printing indications speci c
to the Format module.

The pretty-printing indication characters are introduced by a @ character, and their meanings are:

- @[open a pretty-printing box. The type and o set of the box may be optionally speci ed with the following syntax: the < character, followed by an optional box type indication, then an optional integer o set, and the closing > character. Box type is one of h, v, hv, b, or hov, which stand respectively for an horizontal box, a vertical box, an horizontal-vertical box, or an horizontal or vertical box (b standing for an horizontal or vertical box demonstrating indentation and hov standing for a regular horizontal or vertical box). For instance, @[<hov 2> opens an horizontal or vertical box with indentation 2 as obtained with open_hovbox 2 For more details about boxes, see the various box opening functions open_*box.

- @] close the most recently opened pretty-printing box.

- @; output a good break as with print_cut () .

- @: output a space, as with print_space () .

- @\n force a newline, as with force_newline () .

- @; output a good break as with print_break . The nspaces and offset parameters of the break may be optionally speci ed with the following syntax: the < character, followed by an integer nspaces value, then an integer offset , and a closing > character. If no parameters are provided, the good break defaults to a space.

- @? ush the pretty printer as with print_flush () . This is equivalent to the conversion %!.

- @: ush the pretty printer and output a new line, as with print_newline () .

- @<n> print the following item as if it were of length n. Hence, printf "@<0>%s" arg is equivalent to print_as 0 arg . If @<n> is not followed by a conversion speci cation, then the following character of the format is printed as if it were of length n.

- @{ open a tag. The name of the tag may be optionally speci ed with the following syntax: the < character, followed by an optional string speci cation, and the closing > character. The string speci cation is any character string that does not contain the closing character '>' . If omitted, the tag name defaults to the empty string. For more details about tags, see the functions open_tag and close_tag .

- @} close the most recently opened tag.

- @@ print a plain @ character.

Example: printf "@[%s@ %d@]@." "x =" 1 is equivalent to open_box (); print_string "x ="; print_space (); print_int 1; close_box (); print_newline () . It prints x = 1 within a pretty-printing box.

val printf : ('a, formatter, unit) Pervasives.format -> 'a

    Same as fprintf above, but output on std_formatter .

val eprintf : ('a, formatter, unit) Pervasives.format -> 'a

Same as fprintf above, but output on err_formatter .

val sprintf : ('a, unit, string) Pervasives.format -> 'a

Same as printf above, but instead of printing on a formatter, returns a string containing the result of formatting the arguments. Note that the pretty-printer queue is ushed at the end of each call to sprintf .

In case of multiple and related calls to sprintf to output material on a single string, you should consider using fprintf with the prede ned formatter str_formatter and call flush_str_formatter () to get the nal result.

Alternatively, you can use Format.fprintf with a formatter writing to a bu er of your own: ushing the formatter and the bu er at the end of pretty-printing returns the desired string.

val ifprintf : formatter -> ('a, formatter, unit) Pervasives.format -> 'a

Same as fprintf above, but does not print anything. Useful to ignore some material when conditionally printing.

Since: 3.10.0

Formatted output functions with continuations.

val kfprintf :
  (formatter -> 'a) ->
  formatter -> ('b, formatter, unit, 'a) Pervasives.format4 -> 'b

Same as fprintf above, but instead of returning immediately, passes the formatter to its rst argument at the end of printing.

val ikfprintf :
  (formatter -> 'a) ->
  formatter -> ('b, formatter, unit, 'a) Pervasives.format4 -> 'b

Same as kfprintf above, but does not print anything. Useful to ignore some material when conditionally printing.

Since: 3.12.0

val ksprintf :
  (string -> 'a) -> ('b, unit, string, 'a) Pervasives.format4 -> 'b

Same as sprintf above, but instead of returning the string, passes it to the rst argument.

Deprecated

val bprintf : Buffer.t -> ('a, formatter, unit) Pervasives.format -> 'a

A deprecated and error prone function. Do not use it.

If you need to print to some bu er b, you must rst de ne a formatter writing to b, using let to_b = formatter_of_buffer b ; then use regular calls to Format.fprintf on formatter to_b.

val kprintf :
  (string -> 'a) -> ('b, unit, string, 'a) Pervasives.format4 -> 'b

A deprecated synonym for ksprintf .

14 Module Gc : Memory management control and statistics; -nalised values.

```
type stat = {
  minor_words : float ;
```
>Number of words allocated in the minor heap since the program was started. This number is accurate in byte-code programs, but only an approximation in programs compiled to native code.

```
  promoted_words : float ;
```
>Number of words allocated in the minor heap that survived a minor collection and were moved to the major heap since the program was started.

```
  major_words : float ;
```
>Number of words allocated in the major heap, including the promoted words, since the program was started.

```
  minor_collections : int ;
```
>Number of minor collections since the program was started.

```
  major_collections : int ;
```
>Number of major collection cycles completed since the program was started.

```
  heap_words : int ;
```
>Total size of the major heap, in words.

```
  heap_chunks : int ;
```
>Number of contiguous pieces of memory that make up the major heap.

```
  live_words : int ;
```
>Number of words of live data in the major heap, including the header words.

```
  live_blocks : int ;
```
>Number of live blocks in the major heap.

```
  free_words : int ;
```
>Number of words in the free list.

```
  free_blocks : int ;
```
>Number of blocks in the free list.

```
  largest_free : int ;
```
>Size (in words) of the largest block in the free list.

```
  fragments : int ;
```
>Number of wasted words due to fragmentation. These are 1-words free blocks placed between two live blocks. They are not available for allocation.

```
  compactions : int ;
```

Number of heap compactions since the program was started.

top_heap_words : int ;
    Maximum size reached by the major heap, in words.

stack_size : int ;
    Current size of the stack, in words.
}

The memory management counters are returned in a stat record.

The total amount of memory allocated by the program since it was started is (in words) minor_words + major_words - promoted_words. Multiply by the word size (4 on a 32-bit machine, 8 on a 64-bit machine) to get the number of bytes.

type control = {
mutable minor_heap_size : int ;
    The size (in words) of the minor heap. Changing this parameter will trigger a minor collection. Default: 32k.

mutable major_heap_increment : int ;
    The minimum number of words to add to the major heap when increasing it. Default: 124k.

mutable space_overhead : int ;
    The major GC speed is computed from this parameter. This is the memory that will be "wasted" because the GC does not immediatly collect unreachable blocks. It is expressed as a percentage of the memory used for live data. The GC will work more (use more CPU time and collect blocks more eagerly) if space_overhead is smaller. Default: 80.

mutable verbose : int ;
    This value controls the GC messages on standard error output. It is a sum of some of the following ags, to print messages on the corresponding events:

    - 0x001 Start of major GC cycle.
    - 0x002 Minor collection and major GC slice.
    - 0x004 Growing and shrinking of the heap.
    - 0x008 Resizing of stacks and memory manager tables.
    - 0x010 Heap compaction.
    - 0x020 Change of GC parameters.
    - 0x040 Computation of major GC slice size.
    - 0x080 Calling of nalisation functions.
    - 0x100 Bytecode executable search at start-up.
    - 0x200 Computation of compaction triggering condition. Default: 0.

mutable max_overhead : int ;

35

Heap compaction is triggered when the estimated amount of "wasted" memory is more than max_overhead percent of the amount of live data. If max_overhead is set to 0, heap compaction is triggered at the end of each major GC cycle (this setting is intended for testing purposes only). If max_overhead >= 1000000 compaction is never triggered. Default: 500.

mutable stack_limit : int ;

The maximum size of the stack (in words). This is only relevant to the byte-code runtime, as the native code runtime uses the operating system's stack. Default: 256k.

mutable allocation_policy : int ;

The policy used for allocating in the heap. Possible values are 0 and 1. 0 is the next- t policy, which is quite fast but can result in fragmentation. 1 is the rst- t policy, which can be slower in some cases but can be better for programs with fragmentation problems. Default: 0.

}

The GC parameters are given as a control record. Note that these parameters can also be initialised by setting the OCAMLRUNPARAM environment variable. See the documentation of ocamlrun.

val stat : unit -> stat

Return the current values of the memory management counters in a stat record. This function examines every heap block to get the statistics.

val quick_stat : unit -> stat

Same as stat except that live_words , live_blocks , free_words , free_blocks , largest_free , and fragments are set to 0. This function is much faster than stat because it does not need to go through the heap.

val counters : unit -> float * float * float

Return (minor_words, promoted_words, major_words) . This function is as fast at quick_stat .

val get : unit -> control

Return the current values of the GC parameters in a control record.

val set : control -> unit

set r changes the GC parameters according to the control record r . The normal usage is: Gc.set { (Gc.get()) with Gc.verbose = 0x00d }

val minor : unit -> unit

Trigger a minor collection.

val major_slice : int -> int

Do a minor collection and a slice of major collection. The argument is the size of the slice, 0 to use the automatically-computed slice size. In all cases, the result is the computed slice size.

val major : unit -> unit

Do a minor collection and finish the current major collection cycle.

val full_major : unit -> unit

Do a minor collection, finish the current major collection cycle, and perform a complete new cycle. This will collect all currently unreachable blocks.

val compact : unit -> unit

Perform a full major collection and compact the heap. Note that heap compaction is a lengthy operation.

val print_stat : Pervasives.out_channel -> unit

Print the current values of the memory management counters (in human-readable form) into the channel argument.

val allocated_bytes : unit -> float

Return the total number of bytes allocated since the program was started. It is returned as a float to avoid overflow problems with int on 32-bit machines.

val finalise : ('a -> unit) -> 'a -> unit

finalise f v registers f as a finalisation function for v. v must be heap-allocated. f will be called with v as argument at some point between the first time v becomes unreachable and the time v is collected by the GC. Several functions can be registered for the same value, or even several instances of the same function. Each instance will be called once (or never, if the program terminates before v becomes unreachable).

The GC will call the finalisation functions in the order of deallocation. When several values become unreachable at the same time (i.e. during the same GC cycle), the finalisation functions will be called in the reverse order of the corresponding calls to finalise. If finalise is called in the same order as the values are allocated, that means each value is finalised before the values it depends upon. Of course, this becomes false if additional dependencies are introduced by assignments.

Anything reachable from the closure of finalisation functions is considered reachable, so the following code will not work as expected:

- let v = ... in Gc.finalise (fun x -> ...) v

Instead you should write:

- let f = fun x -> ... ;; let v = ... in Gc.finalise f v

The f function can use all features of O'Caml, including assignments that make the value reachable again. It can also loop forever (in this case, the other nalisation functions will not be called during the execution of f, unless it calls finalise_release). It can call finalise on v or other values to register other functions or even itself. It can raise an exception; in this case the exception will interrupt whatever the program was doing when the function was called.

finalise   will raise Invalid_argument   if v is not heap-allocated. Some examples of values that are not heap-allocated are integers, constant constructors, booleans, the empty array, the empty list, the unit value. The exact list of what is heap-allocated or not is implementation-dependent. Some constant values can be heap-allocated but never deallocated during the lifetime of the program, for example a list of integer constants; this is also implementation-dependent. You should also be aware that compiler optimisations may duplicate some immutable values, for example oating-point numbers when stored into arrays, so they can be nalised and collected while another copy is still in use by the program.

The results of calling String.make [41], String.create   [41], Array.make[2], and Pervasives.ref   [30] are guaranteed to be heap-allocated and non-constant except when the length argument is 0.

val finalise_release : unit -> unit

A nalisation function may call finalise_release   to tell the GC that it can launch the next nalisation function without waiting for the current one to return.

type alarm

An alarm is a piece of data that calls a user function at the end of each major GC cycle. The following functions are provided to create and delete alarms.

val create_alarm : (unit -> unit) -> alarm

create_alarm f   will arrange for f to be called at the end of each major GC cycle, starting with the current cycle or the next one. A value of type alarm is returned that you can use to call delete_alarm .

val delete_alarm : alarm -> unit

delete_alarm a will stop the calls to the function associated to a. Calling delete_alarm a again has no e ect.

15 Module Genlex : A generic lexical analyzer.

This module implements a simple standard lexical analyzer, presented as a function from character streams to token streams. It implements roughly the lexical conventions of Caml, but is parameterized by the set of keywords of your language.

Example: a lexer suitable for a desk calculator is obtained by

    let lexer = make_lexer ["+";"-";"*";"/";"let";"="; "("; ")"]

The associated parser would be a function from token stream to, for instance, int , and would have rules such as:

```
let parse_expr = parser
      [< 'Int n >] -> n
    | [< 'Kwd "("; n = parse_expr; 'Kwd ")" >] -> n
    | [< n1 = parse_expr; n2 = parse_remainder n1 >] -> n2
  and parse_remainder n1 = parser
      [< 'Kwd "+"; n2 = parse_expr >] -> n1+n2
    | ...
```

type token =
  | Kwd of string
  | Ident of string
  | Int of int
  | Float of float
  | String of string
  | Char of char

> The type of tokens. The lexical classes are Int and Float for integer and floating-point numbers; String for string literals, enclosed in double quotes; Char for character literals, enclosed in single quotes; Ident for identifiers (either sequences of letters, digits, underscores and quotes, or sequences of "operator characters" such as +, *, etc); and Kwd for keywords (either identifiers or single "special characters" such as (, }, etc).

val make_lexer : string list -> char Stream.t -> token Stream.t

> Construct the lexer function. The first argument is the list of keywords. An identifier s is returned as Kwd s if s belongs to this list, and as Ident s otherwise. A special character s is returned as Kwd s if s belongs to this list, and cause a lexical error (exception Parse_error) otherwise. Blanks and newlines are skipped. Comments delimited by (* and *) are skipped as well, and can be nested.

16 Module Hashtbl : Hash tables and hash functions.

Hash tables are hashed association tables, with in-place modification.

Generic interface

type ('a, 'b) t

> The type of hash tables from type 'a to type 'b .

val create : int -> ('a, 'b) t

> Hashtbl.create n creates a new, empty hash table, with initial size n. For best results, n should be on the order of the expected number of elements that will be in the table. The table grows as needed, so n is just an initial guess.

val clear : ('a, 'b) t -> unit

    Empty a hash table.

val add : ('a, 'b) t -> 'a -> 'b -> unit

    Hashtbl.add tbl x y   adds a binding of x to y in table tbl . Previous bindings for x are not removed, but simply hidden. That is, after performing Hashtbl.remove [16] tbl x , the previous binding for x, if any, is restored. (Same behavior as with association lists.)

val copy : ('a, 'b) t -> ('a, 'b) t

    Return a copy of the given hashtable.

val find : ('a, 'b) t -> 'a -> 'b

    Hashtbl.find tbl x   returns the current binding of x in tbl , or raises Not_found if no such binding exists.

val find_all : ('a, 'b) t -> 'a -> 'b list

    Hashtbl.find_all tbl x   returns the list of all data associated with x in tbl . The current binding is returned rst, then the previous bindings, in reverse order of introduction in the table.

val mem : ('a, 'b) t -> 'a -> bool

    Hashtbl.mem tbl x checks if x is bound in tbl .

val remove : ('a, 'b) t -> 'a -> unit

    Hashtbl.remove tbl x   removes the current binding of x in tbl , restoring the previous binding if it exists. It does nothing if x is not bound in tbl .

val replace : ('a, 'b) t -> 'a -> 'b -> unit

    Hashtbl.replace tbl x y   replaces the current binding of x in tbl by a binding of x to y. If x is unbound in tbl , a binding of x to y is added to tbl . This is functionally equivalent to Hashtbl.remove [16] tbl x   followed by Hashtbl.add [16] tbl x y .

val iter : ('a -> 'b -> unit) -> ('a, 'b) t -> unit

    Hashtbl.iter f tbl   applies f to all bindings in table tbl . f receives the key as rst argument, and the associated value as second argument. Each binding is presented exactly once to f . The order in which the bindings are passed to f is unspeci ed. However, if the table contains several bindings for the same key, they are passed to f in reverse order of introduction, that is, the most recent binding is passed rst.

val fold : ('a -> 'b -> 'c -> 'c) -> ('a, 'b) t -> 'c -> 'c

    Hashtbl.fold f tbl init   computes (f kN dN ... (f k1 d1 init)...)   , where k1 ... kN are the keys of all bindings in tbl , and d1 ... dN are the associated values. Each binding is presented exactly once to f . The order in which the bindings are passed to f is unspeci ed. However, if the table contains several bindings for the same key, they are passed to f in reverse order of introduction, that is, the most recent binding is passed rst.

val length : ('a, 'b) t -> int

> Hashtbl.length tbl   returns the number of bindings in tbl . Multiple bindings are counted multiply, so Hashtbl.length   gives the number of times Hashtbl.iter   calls its rst argument.

Functorial interface

module type HashedType =
  sig

> type t

>> The type of the hashtable keys.

> val equal : t -> t -> bool

>> The equality predicate used to compare keys.

> val hash : t -> int

>> A hashing function on keys. It must be such that if two keys are equal according to equal, then they have identical hash values as computed by hash. Examples: suitable (equal, hash) pairs for arbitrary key types include ((=) , Hashtbl.hash [16]) for comparing objects by structure, ((fun x y -> compare x y = 0) , Hashtbl.hash [16]) for comparing objects by structure and handling Pervasives.nan [30] correctly, and ((==) , Hashtbl.hash [16]) for comparing objects by addresses (e.g. for cyclic keys).

  end

> The input signature of the functor Hashtbl.Make [16].

module type S =
  sig

> type key
> type 'a t
> val create : int -> 'a t
> val clear : 'a t -> unit
> val copy : 'a t -> 'a t
> val add : 'a t -> key -> 'a -> unit
> val remove : 'a t -> key -> unit
> val find : 'a t -> key -> 'a
> val find_all : 'a t -> key -> 'a list
> val replace : 'a t -> key -> 'a -> unit
> val mem : 'a t -> key -> bool
> val iter : (key -> 'a -> unit) -> 'a t -> unit
> val fold : (key -> 'a -> 'b -> 'b) -> 'a t -> 'b -> 'b
> val length : 'a t -> int

end

The output signature of the functor Hashtbl.Make[16].

module Make :
  functor (H : HashedType) -> S   with type key = H.t

  Functor building an implementation of the hashtable structure. The functor Hashtbl.Make returns a structure containing a type key of keys and a type 'a t of hash tables associating data of type 'a to keys of type key. The operations perform similarly to those of the generic interface, but use the hashing and equality functions speci ed in the functor argument H instead of generic equality and hashing.

The polymorphic hash primitive

val hash : 'a -> int

  Hashtbl.hash x associates a positive integer to any value of any type. It is guaranteed that if x = y or Pervasives.compare x y = 0, then hash x = hash y. Moreover, hash always terminates, even on cyclic structures.

val hash_param : int -> int -> 'a -> int

  Hashtbl.hash_param n m x computes a hash value for x, with the same properties as for hash. The two extra parameters n and m give more precise control over hashing. Hashing performs a depth- rst, right-to-left traversal of the structure x, stopping after n meaningful nodes were encountered, or m nodes, meaningful or not, were encountered. Meaningful nodes are: integers; oating-point numbers; strings; characters; booleans; and constant constructors. Larger values of m and n means that more nodes are taken into account to compute the nal hash value, and therefore collisions are less likely to happen. However, hashing takes longer. The parameters m and n govern the tradeo between accuracy and speed.

17   Module Int32 : 32-bit integers.

This module provides operations on the type int32 of signed 32-bit integers. Unlike the built-in int type, the type int32 is guaranteed to be exactly 32-bit wide on all platforms. All arithmetic operations over int32 are taken modulo 2^{32}.

Performance notice: values of type int32 occupy more memory space than values of type int, and arithmetic operations on int32 are generally slower than those on int. Use int32 only when the application requires exact 32-bit arithmetic.

val zero : int32

  The 32-bit integer 0.

val one : int32

  The 32-bit integer 1.

val minus_one : int32

The 32-bit integer -1.

val neg : int32 -> int32
    Unary negation.

val add : int32 -> int32 -> int32
    Addition.

val sub : int32 -> int32 -> int32
    Subtraction.

val mul : int32 -> int32 -> int32
    Multiplication.

val div : int32 -> int32 -> int32
    Integer division. Raise Division_by_zero if the second argument is zero. This division
    rounds the real quotient of its arguments towards zero, as speci ed for Pervasives.(/) [30].

val rem : int32 -> int32 -> int32
    Integer remainder. If y is not zero, the result of Int32.rem x y satis es the following
    property: x = Int32.add (Int32.mul (Int32.div x y) y) (Int32.rem x y) . If y = 0,
    Int32.rem x y raises Division_by_zero .

val succ : int32 -> int32
    Successor. Int32.succ x is Int32.add x Int32.one .

val pred : int32 -> int32
    Predecessor. Int32.pred x is Int32.sub x Int32.one .

val abs : int32 -> int32
    Return the absolute value of its argument.

val max_int : int32
    The greatest representable 32-bit integer, 2^{31} - 1.

val min_int : int32
    The smallest representable 32-bit integer, -2^{31}.

val logand : int32 -> int32 -> int32
    Bitwise logical and.

val logor : int32 -> int32 -> int32
    Bitwise logical or.

val logxor : int32 -> int32 -> int32

Bitwise logical exclusive or.

val lognot : int32 -> int32

    Bitwise logical negation

val shift_left : int32 -> int -> int32

    Int32.shift_left x y   shifts x to the left by y bits. The result is unspecied if y < 0 or y >= 32

val shift_right : int32 -> int -> int32

    Int32.shift_right x y   shifts x to the right by y bits. This is an arithmetic shift: the sign bit of x is replicated and inserted in the vacated bits. The result is unspecied if y < 0 or y >= 32

val shift_right_logical : int32 -> int -> int32

    Int32.shift_right_logical x y   shifts x to the right by y bits. This is a logical shift: zeroes are inserted in the vacated bits regardless of the sign of x. The result is unspecied if y < 0 or y >= 32

val of_int : int -> int32

    Convert the given integer (type int) to a 32-bit integer (type int32).

val to_int : int32 -> int

    Convert the given 32-bit integer (type int32) to an integer (type int). On 32-bit platforms, the 32-bit integer is taken modulo 2^{31}, i.e. the high-order bit is lost during the conversion. On 64-bit platforms, the conversion is exact.

val of_float : float -> int32

    Convert the given oating-point number to a 32-bit integer, discarding the fractional part (truncate towards 0). The result of the conversion is undened if, after truncation, the number is outside the range [Int32.min_int [17], Int32.max_int [17]].

val to_float : int32 -> float

    Convert the given 32-bit integer to a oating-point number.

val of_string : string -> int32

    Convert the given string to a 32-bit integer. The string is read in decimal (by default) or in hexadecimal, octal or binary if the string begins with 0x, 0o or 0b respectively. Raise Failure "int_of_string"   if the given string is not a valid representation of an integer, or if the integer represented exceeds the range of integers representable in type int32 .

val to_string : int32 -> string

    Return the string representation of its argument, in signed decimal.

val bits_of_float : float -> int32

Return the internal representation of the given oat according to the IEEE 754
 oating-point single format bit layout. Bit 31 of the result represents the sign of the oat;
bits 30 to 23 represent the (biased) exponent; bits 22 to 0 represent the mantissa.

val float_of_bits : int32 -> float

Return the oating-point number whose internal representation, according to the IEEE 754
 oating-point single format bit layout, is the given int32 .

type t = int32

An alias for the type of 32-bit integers.

val compare : t -> t -> int

The comparison function for 32-bit integers, with the same speci cation as
Pervasives.compare [30]. Along with the type t , this function compare allows the module
Int32 to be passed as argument to the functors Set.Make [36] and Map.Make [23].

18   Module Int64 : 64-bit integers.

This module provides operations on the type int64 of signed 64-bit integers. Unlike the built-in
int type, the type int64 is guaranteed to be exactly 64-bit wide on all platforms. All arithmetic
operations over int64 are taken modulo 2^{64}

Performance notice: values of type int64 occupy more memory space than values of type int ,
and arithmetic operations on int64 are generally slower than those on int . Use int64 only when
the application requires exact 64-bit arithmetic.

val zero : int64

The 64-bit integer 0.

val one : int64

The 64-bit integer 1.

val minus_one : int64

The 64-bit integer -1.

val neg : int64 -> int64

Unary negation.

val add : int64 -> int64 -> int64

Addition.

val sub : int64 -> int64 -> int64

Subtraction.

val mul : int64 -> int64 -> int64

Multiplication.

val div : int64 -> int64 -> int64

> Integer division. Raise `Division_by_zero` if the second argument is zero. This division rounds the real quotient of its arguments towards zero, as specified for `Pervasives.(/)` [30].

val rem : int64 -> int64 -> int64

> Integer remainder. If y is not zero, the result of `Int64.rem x y` satisfies the following property: `x = Int64.add (Int64.mul (Int64.div x y) y) (Int64.rem x y)`. If y = 0, `Int64.rem x y` raises `Division_by_zero`.

val succ : int64 -> int64

> Successor. `Int64.succ x` is `Int64.add x Int64.one`.

val pred : int64 -> int64

> Predecessor. `Int64.pred x` is `Int64.sub x Int64.one`.

val abs : int64 -> int64

> Return the absolute value of its argument.

val max_int : int64

> The greatest representable 64-bit integer, 2^{63} - 1.

val min_int : int64

> The smallest representable 64-bit integer, -2^{63}.

val logand : int64 -> int64 -> int64

> Bitwise logical and.

val logor : int64 -> int64 -> int64

> Bitwise logical or.

val logxor : int64 -> int64 -> int64

> Bitwise logical exclusive or.

val lognot : int64 -> int64

> Bitwise logical negation

val shift_left : int64 -> int -> int64

> `Int64.shift_left x y` shifts x to the left by y bits. The result is unspecified if y < 0 or y >= 64.

val shift_right : int64 -> int -> int64

> `Int64.shift_right x y` shifts x to the right by y bits. This is an arithmetic shift: the sign bit of x is replicated and inserted in the vacated bits. The result is unspecified if y < 0 or y >= 64.

val shift_right_logical : int64 -> int -> int64

Int64.shift_right_logical x y shifts x to the right by y bits. This is a logical shift: zeroes are inserted in the vacated bits regardless of the sign of x. The result is unspecified if y < 0 or y >= 64.

val of_int : int -> int64

Convert the given integer (type int) to a 64-bit integer (type int64).

val to_int : int64 -> int

Convert the given 64-bit integer (type int64) to an integer (type int). On 64-bit platforms, the 64-bit integer is taken modulo 2^{63}, i.e. the high-order bit is lost during the conversion. On 32-bit platforms, the 64-bit integer is taken modulo 2^{31}, i.e. the top 33 bits are lost during the conversion.

val of_float : float -> int64

Convert the given floating-point number to a 64-bit integer, discarding the fractional part (truncate towards 0). The result of the conversion is undefined if, after truncation, the number is outside the range [Int64.min_int [18], Int64.max_int [18]].

val to_float : int64 -> float

Convert the given 64-bit integer to a floating-point number.

val of_int32 : int32 -> int64

Convert the given 32-bit integer (type int32) to a 64-bit integer (type int64).

val to_int32 : int64 -> int32

Convert the given 64-bit integer (type int64) to a 32-bit integer (type int32). The 64-bit integer is taken modulo 2^{32}, i.e. the top 32 bits are lost during the conversion.

val of_nativeint : nativeint -> int64

Convert the given native integer (type nativeint) to a 64-bit integer (type int64).

val to_nativeint : int64 -> nativeint

Convert the given 64-bit integer (type int64) to a native integer. On 32-bit platforms, the 64-bit integer is taken modulo 2^{32}. On 64-bit platforms, the conversion is exact.

val of_string : string -> int64

Convert the given string to a 64-bit integer. The string is read in decimal (by default) or in hexadecimal, octal or binary if the string begins with 0x, 0o or 0b respectively. Raise Failure "int_of_string" if the given string is not a valid representation of an integer, or if the integer represented exceeds the range of integers representable in type int64 .

val to_string : int64 -> string

Return the string representation of its argument, in decimal.

val bits_of_float : float -> int64

> Return the internal representation of the given oat according to the IEEE 754
> oating-point double format bit layout. Bit 63 of the result represents the sign of the oat;
> bits 62 to 52 represent the (biased) exponent; bits 51 to 0 represent the mantissa.

val float_of_bits : int64 -> float

> Return the oating-point number whose internal representation, according to the IEEE 754
> oating-point double format bit layout, is the given int64 .

type t = int64

> An alias for the type of 64-bit integers.

val compare : t -> t -> int

> The comparison function for 64-bit integers, with the same speci cation as
> Pervasives.compare [30]. Along with the type t , this function compare allows the module
> Int64 to be passed as argument to the functors Set.Make [36] and Map.Make [23].

19 Module Lazy : Deferred computations.

type 'a t = 'a lazy_t

> A value of type 'a Lazy.t is a deferred computation, called a suspension, that has a result
> of type 'a . The special expression syntax lazy (expr) makes a suspension of the
> computation of expr , without computing expr itself yet. "Forcing" the suspension will then
> compute expr and return its result.

> Note: lazy_t is the built-in type constructor used by the compiler for the lazy keyword.
> You should not use it directly. Always use Lazy.t instead.

> Note: Lazy.force is not thread-safe. If you use this module in a multi-threaded program,
> you will need to add some locks.

> Note: if the program is compiled with the -rectypes option, ill-founded recursive de nitions
> of the form let rec x = lazy x or let rec x = lazy(lazy(...(lazy x))) are accepted
> by the type-checker and lead, when forced, to ill-formed values that trigger in nite loops in
> the garbage collector and other parts of the run-time system. Without the -rectypes
> option, such ill-founded recursive de nitions are rejected by the type-checker.

exception Undefined

val force : 'a t -> 'a

force x forces the suspension x and returns its result. If x has already been forced, Lazy.force
x returns the same value again without recomputing it. If it raised an exception, the same exception
is raised again. Raise Undefined if the forcing of x tries to force x itself recursively.

val force_val : 'a t -> 'a

force_val x forces the suspension x and returns its result. If x has already been forced, force_val x returns the same value again without recomputing it. Raise Undefined if the forcing of x tries to force x itself recursively. If the computation of x raises an exception, it is unspeci ed whether force_val x raises the same exception or Undefined.

val lazy_from_fun : (unit -> 'a) -> 'a t

lazy_from_fun f is the same as lazy (f ()) but slightly more e cient.

val lazy_from_val : 'a -> 'a t

lazy_from_val v returns an already-forced suspension of v. This is for special purposes only and should not be confused with lazy (v) .

val lazy_is_val : 'a t -> bool

lazy_is_val x returns true if x has already been forced and did not raise an exception.

20 Module Lexing : The run-time library for lexers generated by ocamllex .

Positions
```
type position = {
  pos_fname : string ;
  pos_lnum : int ;
  pos_bol : int ;
  pos_cnum : int ;
}
```

A value of type position describes a point in a source le. pos_fname is the le name; pos_lnum is the line number; pos_bol is the o set of the beginning of the line (number of characters between the beginning of the le and the beginning of the line); pos_cnum is the o set of the position (number of characters between the beginning of the le and the position).

See the documentation of type lexbuf for information about how the lexing engine will manage positions.

val dummy_pos : position

A value of type position , guaranteed to be di erent from any valid position.

Lexer bu ers
```
type lexbuf = {
  refill_buff : lexbuf -> unit ;
  mutable lex_buffer : string ;
  mutable lex_buffer_len : int ;
  mutable lex_abs_pos : int ;
```

```
    mutable lex_start_pos : int ;
    mutable lex_curr_pos : int ;
    mutable lex_last_pos : int ;
    mutable lex_last_action : int ;
    mutable lex_eof_reached : bool ;
    mutable lex_mem : int array ;
    mutable lex_start_p : position ;
    mutable lex_curr_p : position ;
}
```

The type of lexer bu ers. A lexer bu er is the argument passed to the scanning functions de ned by the generated scanners. The lexer bu er holds the current state of the scanner, plus a function to re ll the bu er from the input.

At each token, the lexing engine will copy lex_curr_p to lex_start_p , then change the pos_cnum eld of lex_curr_p by updating it with the number of characters read since the start of the lexbuf . The other elds are left unchanged by the lexing engine. In order to keep them accurate, they must be initialised before the rst use of the lexbuf, and updated by the relevant lexer actions (i.e. at each end of line see also new_line).

val from_channel : Pervasives.in_channel -> lexbuf

Create a lexer bu er on the given input channel. Lexing.from_channel inchan returns a lexer bu er which reads from the input channel inchan , at the current reading position.

val from_string : string -> lexbuf

Create a lexer bu er which reads from the given string. Reading starts from the rst character in the string. An end-of-input condition is generated when the end of the string is reached.

val from_function : (string -> int -> int) -> lexbuf

Create a lexer bu er with the given function as its reading method. When the scanner needs more characters, it will call the given function, giving it a character string s and a character count n. The function should put n characters or less in s, starting at character number 0, and return the number of characters provided. A return value of 0 means end of input.

Functions for lexer semantic actions

The following functions can be called from the semantic actions of lexer de nitions (the ML code enclosed in braces that computes the value returned by lexing functions). They give access to the character string matched by the regular expression associated with the semantic action. These functions must be applied to the argument lexbuf , which, in the code generated by ocamllex , is bound to the lexer bu er passed to the parsing function.

val lexeme : lexbuf -> string

Lexing.lexeme lexbuf returns the string matched by the regular expression.

val lexeme_char : lexbuf -> int -> char

Lexing.lexeme_char lexbuf i returns character number i in the matched string.

val lexeme_start : lexbuf -> int

> Lexing.lexeme_start lexbuf   returns the o set in the input stream of the rst character of the matched string. The rst character of the stream has o set 0.

val lexeme_end : lexbuf -> int

> Lexing.lexeme_end lexbuf   returns the o set in the input stream of the character following the last character of the matched string. The rst character of the stream has o set 0.

val lexeme_start_p : lexbuf -> position

> Like lexeme_start , but return a complete position   instead of an o set.

val lexeme_end_p : lexbuf -> position

> Like lexeme_end, but return a complete position   instead of an o set.

val new_line : lexbuf -> unit

> Update the lex_curr_p   eld of the lexbuf to re ect the start of a new line. You can call this function in the semantic action of the rule that matches the end-of-line character.
>
> Since: 3.11.0

Miscellaneous functions

val flush_input : lexbuf -> unit

> Discard the contents of the bu er and reset the current position to 0. The next use of the lexbuf will trigger a re ll.

21   Module List : List operations.

Some functions are agged as not tail-recursive. A tail-recursive function uses constant stack space, while a non-tail-recursive function uses stack space proportional to the length of its list argument, which can be a problem with very long lists. When the function takes several list arguments, an approximate formula giving stack usage (in some unspeci ed constant unit) is shown in parentheses.

The above considerations can usually be ignored if your lists are not longer than about 10000 elements.

val length : 'a list -> int

> Return the length (number of elements) of the given list.

val hd : 'a list -> 'a

> Return the rst element of the given list. Raise Failure "hd"   if the list is empty.

val tl : 'a list -> 'a list

> Return the given list without its rst element. Raise Failure "tl"   if the list is empty.

val nth : 'a list -> int -> 'a

Return the n-th element of the given list. The rst element (head of the list) is at position 0. Raise Failure "nth" if the list is too short. Raise Invalid_argument "List.nth" if n is negative.

val rev : 'a list -> 'a list
    List reversal.

val append : 'a list -> 'a list -> 'a list
    Catenate two lists. Same function as the in x operator @ Not tail-recursive (length of the rst argument). The @ operator is not tail-recursive either.

val rev_append : 'a list -> 'a list -> 'a list
    List.rev_append l1 l2 reverses l1 and concatenates it to l2 . This is equivalent to List.rev [21] l1 @ l2, but rev_append is tail-recursive and more e cient.

val concat : 'a list list -> 'a list
    Concatenate a list of lists. The elements of the argument are all concatenated together (in the same order) to give the result. Not tail-recursive (length of the argument + length of the longest sub-list).

val flatten : 'a list list -> 'a list
    Same as concat . Not tail-recursive (length of the argument + length of the longest sub-list).

    Iterators

val iter : ('a -> unit) -> 'a list -> unit
    List.iter f [a1; ...; an] applies function f in turn to a1; ...; an . It is equivalent to begin f a1; f a2; ...; f an; () end .

val map : ('a -> 'b) -> 'a list -> 'b list
    List.map f [a1; ...; an] applies function f to a1, ..., an , and builds the list [f a1; ...; f an] with the results returned by f . Not tail-recursive.

val rev_map : ('a -> 'b) -> 'a list -> 'b list
    List.rev_map f l gives the same result as List.rev [21] (List.map [21] f l) , but is tail-recursive and more e cient.

val fold_left : ('a -> 'b -> 'a) -> 'a -> 'b list -> 'a
    List.fold_left f a [b1; ...; bn] is f (... (f (f a b1) b2) ...) bn .

val fold_right : ('a -> 'b -> 'b) -> 'a list -> 'b -> 'b
    List.fold_right f [a1; ...; an] b is f a1 (f a2 (... (f an b) ...)) . Not tail-recursive.

    Iterators on two lists

val iter2 : ('a -> 'b -> unit) -> 'a list -> 'b list -> unit

List.iter2 f [a1; ...; an] [b1; ...; bn]   calls in turn f a1 b1; ...; f an bn . Raise Invalid_argument if the two lists have di erent lengths.

val map2 : ('a -> 'b -> 'c) -> 'a list -> 'b list -> 'c list

List.map2 f [a1; ...; an] [b1; ...; bn]   is [f a1 b1; ...; f an bn] . Raise Invalid_argument if the two lists have di erent lengths. Not tail-recursive.

val rev_map2 : ('a -> 'b -> 'c) -> 'a list -> 'b list -> 'c list

List.rev_map2 f l1 l2   gives the same result as List.rev [21] (List.map2 [21] f l1 l2) , but is tail-recursive and more e cient.

val fold_left2 : ('a -> 'b -> 'c -> 'a) -> 'a -> 'b list -> 'c list -> 'a

List.fold_left2 f a [b1; ...; bn] [c1; ...; cn]   is f (... (f (f a b1 c1) b2 c2) ...) bn cn . Raise Invalid_argument if the two lists have di erent lengths.

val fold_right2 : ('a -> 'b -> 'c -> 'c) -> 'a list -> 'b list -> 'c -> 'c

List.fold_right2 f [a1; ...; an] [b1; ...; bn] c   is f a1 b1 (f a2 b2 (... (f an bn c) ...)) . Raise Invalid_argument if the two lists have di erent lengths. Not tail-recursive.

List scanning

val for_all : ('a -> bool) -> 'a list -> bool

for_all p [a1; ...; an]   checks if all elements of the list satisfy the predicate p. That is, it returns (p a1) && (p a2) && ... && (p an) .

val exists : ('a -> bool) -> 'a list -> bool

exists p [a1; ...; an]   checks if at least one element of the list satis es the predicate p. That is, it returns (p a1) || (p a2) || ... || (p an) .

val for_all2 : ('a -> 'b -> bool) -> 'a list -> 'b list -> bool

Same as List.for_all [21], but for a two-argument predicate. Raise Invalid_argument if the two lists have di erent lengths.

val exists2 : ('a -> 'b -> bool) -> 'a list -> 'b list -> bool

Same as List.exists [21], but for a two-argument predicate. Raise Invalid_argument if the two lists have di erent lengths.

val mem : 'a -> 'a list -> bool

mem a l is true if and only if a is equal to an element of l .

val memq : 'a -> 'a list -> bool

Same as List.mem [21], but uses physical equality instead of structural equality to compare list elements.

List searching

val find : ('a -> bool) -> 'a list -> 'a

find p l   returns the ﬁrst element of the list l that satisﬁes the predicate p. Raise Not_found if there is no value that satisﬁes p in the list l.

val filter : ('a -> bool) -> 'a list -> 'a list

filter p l   returns all the elements of the list l that satisfy the predicate p. The order of the elements in the input list is preserved.

val find_all : ('a -> bool) -> 'a list -> 'a list

find_all   is another name for List.filter   [21].

val partition : ('a -> bool) -> 'a list -> 'a list * 'a list

partition p l   returns a pair of lists (l1, l2) , where l1 is the list of all the elements of l that satisfy the predicate p, and l2 is the list of all the elements of l that do not satisfy p. The order of the elements in the input list is preserved.

Association lists

val assoc : 'a -> ('a * 'b) list -> 'b

assoc a l returns the value associated with key a in the list of pairs l. That is, assoc a [...; (a,b); ...] = b   if (a,b) is the leftmost binding of a in list l. Raise Not_found if there is no value associated with a in the list l.

val assq : 'a -> ('a * 'b) list -> 'b

Same as List.assoc [21], but uses physical equality instead of structural equality to compare keys.

val mem_assoc : 'a -> ('a * 'b) list -> bool

Same as List.assoc [21], but simply return true if a binding exists, and false if no bindings exist for the given key.

val mem_assq : 'a -> ('a * 'b) list -> bool

Same as List.mem_assoc [21], but uses physical equality instead of structural equality to compare keys.

val remove_assoc : 'a -> ('a * 'b) list -> ('a * 'b) list

remove_assoc a l returns the list of pairs l without the ﬁrst pair with key a, if any. Not tail-recursive.

val remove_assq : 'a -> ('a * 'b) list -> ('a * 'b) list

Same as List.remove_assoc [21], but uses physical equality instead of structural equality to compare keys. Not tail-recursive.

Lists of pairs

val split : ('a * 'b) list -> 'a list * 'b list

Transform a list of pairs into a pair of lists: split [(a1,b1); ...; (an,bn)]   is ([a1; ...; an], [b1; ...; bn])   . Not tail-recursive.

val combine : 'a list -> 'b list -> ('a * 'b) list

> Transform a pair of lists into a list of pairs: combine [a1; ...; an] [b1; ...; bn] is [(a1,b1); ...; (an,bn)] . Raise Invalid_argument if the two lists have di erent lengths. Not tail-recursive.

Sorting

val sort : ('a -> 'a -> int) -> 'a list -> 'a list

> Sort a list in increasing order according to a comparison function. The comparison function must return 0 if its arguments compare as equal, a positive integer if the rst is greater, and a negative integer if the rst is smaller (see Array.sort for a complete speci cation). For example, Pervasives.compare [30] is a suitable comparison function. The resulting list is sorted in increasing order. List.sort is guaranteed to run in constant heap space (in addition to the size of the result list) and logarithmic stack space.

> The current implementation uses Merge Sort. It runs in constant heap space and logarithmic stack space.

val stable_sort : ('a -> 'a -> int) -> 'a list -> 'a list

> Same as List.sort [21], but the sorting algorithm is guaranteed to be stable (i.e. elements that compare equal are kept in their original order) .

> The current implementation uses Merge Sort. It runs in constant heap space and logarithmic stack space.

val fast_sort : ('a -> 'a -> int) -> 'a list -> 'a list

> Same as List.sort [21] or List.stable_sort [21], whichever is faster on typical input.

val merge : ('a -> 'a -> int) -> 'a list -> 'a list -> 'a list

> Merge two lists: Assuming that l1 and l2 are sorted according to the comparison function cmp, merge cmp l1 l2 will return a sorted list containting all the elements of l1 and l2 . If several elements compare equal, the elements of l1 will be before the elements of l2 . Not tail-recursive (sum of the lengths of the arguments).

22   Module ListLabels : List operations.

Some functions are agged as not tail-recursive. A tail-recursive function uses constant stack space, while a non-tail-recursive function uses stack space proportional to the length of its list argument, which can be a problem with very long lists. When the function takes several list arguments, an approximate formula giving stack usage (in some unspeci ed constant unit) is shown in parentheses.

The above considerations can usually be ignored if your lists are not longer than about 10000 elements.

val length : 'a list -> int

> Return the length (number of elements) of the given list.

val hd : 'a list -> 'a

    Return the rst element of the given list. Raise Failure "hd" if the list is empty.

val tl : 'a list -> 'a list

    Return the given list without its rst element. Raise Failure "tl" if the list is empty.

val nth : 'a list -> int -> 'a

    Return the n-th element of the given list. The rst element (head of the list) is at position 0. Raise Failure "nth" if the list is too short. Raise Invalid_argument "List.nth" if n is negative.

val rev : 'a list -> 'a list

    List reversal.

val append : 'a list -> 'a list -> 'a list

    Catenate two lists. Same function as the in x operator @ Not tail-recursive (length of the rst argument). The @operator is not tail-recursive either.

val rev_append : 'a list -> 'a list -> 'a list

    List.rev_append l1 l2 reverses l1 and concatenates it to l2 . This is equivalent to ListLabels.rev [22] l1 @ l2, but rev_append is tail-recursive and more e cient.

val concat : 'a list list -> 'a list

    Concatenate a list of lists. The elements of the argument are all concatenated together (in the same order) to give the result. Not tail-recursive (length of the argument + length of the longest sub-list).

val flatten : 'a list list -> 'a list

    Same as concat . Not tail-recursive (length of the argument + length of the longest sub-list).

   Iterators

val iter : f:('a -> unit) -> 'a list -> unit

    List.iter f [a1; ...; an] applies function f in turn to a1; ...; an . It is equivalent to begin f a1; f a2; ...; f an; () end .

val map : f:('a -> 'b) -> 'a list -> 'b list

    List.map f [a1; ...; an] applies function f to a1, ..., an , and builds the list [f a1; ...; f an] with the results returned by f . Not tail-recursive.

val rev_map : f:('a -> 'b) -> 'a list -> 'b list

    List.rev_map f l gives the same result as ListLabels.rev [22] (ListLabels.map [22] f l) , but is tail-recursive and more e cient.

val fold_left : f:('a -> 'b -> 'a) -> init:'a -> 'b list -> 'a

    List.fold_left f a [b1; ...; bn] is f (... (f (f a b1) b2) ...) bn .

val fold_right : f:('a -> 'b -> 'b) -> 'a list -> init:'b -> 'b

    List.fold_right f [a1; ...; an] b   is f a1 (f a2 (... (f an b) ...))   . Not tail-recursive.

  Iterators on two lists

val iter2 : f:('a -> 'b -> unit) -> 'a list -> 'b list -> unit

    List.iter2 f [a1; ...; an] [b1; ...; bn]   calls in turn f a1 b1; ...; f an bn . Raise Invalid_argument if the two lists have di erent lengths.

val map2 : f:('a -> 'b -> 'c) -> 'a list -> 'b list -> 'c list

    List.map2 f [a1; ...; an] [b1; ...; bn]   is [f a1 b1; ...; f an bn]   . Raise Invalid_argument if the two lists have di erent lengths. Not tail-recursive.

val rev_map2 : f:('a -> 'b -> 'c) -> 'a list -> 'b list -> 'c list

    List.rev_map2 f l1 l2   gives the same result as ListLabels.rev [22] (ListLabels.map2 [22] f l1 l2)   , but is tail-recursive and more e cient.

val fold_left2 :

  f:('a -> 'b -> 'c -> 'a) -> init:'a -> 'b list -> 'c list -> 'a

    List.fold_left2 f a [b1; ...; bn] [c1; ...; cn]   is f (... (f (f a b1 c1) b2 c2) ...) bn cn . Raise Invalid_argument if the two lists have di erent lengths.

val fold_right2 :

  f:('a -> 'b -> 'c -> 'c) -> 'a list -> 'b list -> init:'c -> 'c

    List.fold_right2 f [a1; ...; an] [b1; ...; bn] c   is f a1 b1 (f a2 b2 (... (f an bn c) ...))   . Raise Invalid_argument if the two lists have di erent lengths. Not tail-recursive.

  List scanning

val for_all : f:('a -> bool) -> 'a list -> bool

    for_all p [a1; ...; an]   checks if all elements of the list satisfy the predicate p. That is, it returns (p a1) && (p a2) && ... && (p an) .

val exists : f:('a -> bool) -> 'a list -> bool

    exists p [a1; ...; an]   checks if at least one element of the list satis es the predicate p. That is, it returns (p a1) || (p a2) || ... || (p an)   .

val for_all2 : f:('a -> 'b -> bool) -> 'a list -> 'b list -> bool

    Same as ListLabels.for_all   [22], but for a two-argument predicate. Raise Invalid_argument if the two lists have di erent lengths.

val exists2 : f:('a -> 'b -> bool) -> 'a list -> 'b list -> bool

    Same as ListLabels.exists   [22], but for a two-argument predicate. Raise Invalid_argument if the two lists have di erent lengths.

val mem : 'a -> set:'a list -> bool

>   mem a l is true if and only if a is equal to an element of l .

val memq : 'a -> set:'a list -> bool

>   Same as ListLabels.mem [22], but uses physical equality instead of structural equality to compare list elements.

List searching

val find : f:('a -> bool) -> 'a list -> 'a

>   find p l   returns the rst element of the list l that satis es the predicate p. Raise Not_found if there is no value that satis es p in the list l .

val filter : f:('a -> bool) -> 'a list -> 'a list

>   filter p l   returns all the elements of the list l that satisfy the predicate p. The order of the elements in the input list is preserved.

val find_all : f:('a -> bool) -> 'a list -> 'a list

>   find_all   is another name for ListLabels.filter   [22].

val partition : f:('a -> bool) -> 'a list -> 'a list * 'a list

>   partition p l   returns a pair of lists (l1, l2)   , where l1 is the list of all the elements of l that satisfy the predicate p, and l2 is the list of all the elements of l that do not satisfy p. The order of the elements in the input list is preserved.

Association lists

val assoc : 'a -> ('a * 'b) list -> 'b

>   assoc a l returns the value associated with key a in the list of pairs l . That is, assoc a [...; (a,b); ...]   = b   if (a,b) is the leftmost binding of a in list l . Raise Not_found if there is no value associated with a in the list l .

val assq : 'a -> ('a * 'b) list -> 'b

>   Same as ListLabels.assoc   [22], but uses physical equality instead of structural equality to compare keys.

val mem_assoc : 'a -> map:('a * 'b) list -> bool

>   Same as ListLabels.assoc   [22], but simply return true if a binding exists, and false if no bindings exist for the given key.

val mem_assq : 'a -> map:('a * 'b) list -> bool

>   Same as ListLabels.mem_assoc [22], but uses physical equality instead of structural equality to compare keys.

val remove_assoc : 'a -> ('a * 'b) list -> ('a * 'b) list

>   remove_assoc a l returns the list of pairs l without the rst pair with key   a, if any. Not tail-recursive.

val remove_assq : 'a -> ('a * 'b) list -> ('a * 'b) list

> Same as ListLabels.remove_assoc [22], but uses physical equality instead of structural equality to compare keys. Not tail-recursive.

Lists of pairs

val split : ('a * 'b) list -> 'a list * 'b list

> Transform a list of pairs into a pair of lists: split [(a1,b1); ...; (an,bn)] is ([a1; ...; an], [b1; ...; bn]) . Not tail-recursive.

val combine : 'a list -> 'b list -> ('a * 'b) list

> Transform a pair of lists into a list of pairs: combine [a1; ...; an] [b1; ...; bn] is [(a1,b1); ...; (an,bn)] . Raise Invalid_argument if the two lists have di erent lengths. Not tail-recursive.

Sorting

val sort : cmp:('a -> 'a -> int) -> 'a list -> 'a list

> Sort a list in increasing order according to a comparison function. The comparison function must return 0 if its arguments compare as equal, a positive integer if the rst is greater, and a negative integer if the rst is smaller (see Array.sort for a complete speci cation). For example, Pervasives.compare [30] is a suitable comparison function. The resulting list is sorted in increasing order. List.sort is guaranteed to run in constant heap space (in addition to the size of the result list) and logarithmic stack space.

> The current implementation uses Merge Sort. It runs in constant heap space and logarithmic stack space.

val stable_sort : cmp:('a -> 'a -> int) -> 'a list -> 'a list

> Same as ListLabels.sort [22], but the sorting algorithm is guaranteed to be stable (i.e. elements that compare equal are kept in their original order) .

> The current implementation uses Merge Sort. It runs in constant heap space and logarithmic stack space.

val fast_sort : cmp:('a -> 'a -> int) -> 'a list -> 'a list

> Same as List.sort [21] or List.stable_sort [21], whichever is faster on typical input.

val merge : cmp:('a -> 'a -> int) -> 'a list -> 'a list -> 'a list

> Merge two lists: Assuming that l1 and l2 are sorted according to the comparison function cmp, merge cmp l1 l2 will return a sorted list containting all the elements of l1 and l2 . If several elements compare equal, the elements of l1 will be before the elements of l2 . Not tail-recursive (sum of the lengths of the arguments).

23 Module Map: Association tables over ordered types.

This module implements applicative association tables, also known as nite maps or dictionaries, given a total ordering function over the keys. All operations over maps are purely applicative (no side-e ects). The implementation uses balanced binary trees, and therefore searching and insertion take time logarithmic in the size of the map.

```
module type OrderedType =
  sig
```

> type t
>
>> The type of the map keys.
>
> val compare : t -> t -> int
>
>> A total ordering function over the keys. This is a two-argument function f such that f
>> e1 e2 is zero if the keyse1 and e2 are equal,f e1 e2 is strictly negative if e1 is
>> smaller than e2, and f e1 e2 is strictly positive if e1 is greater than e2. Example: a
>> suitable ordering function is the generic structural comparison function
>> Pervasives.compare [30].

```
  end
```

> Input signature of the functor Map.Make[23].

```
module type S =
  sig
```

> type key
>
>> The type of the map keys.
>
> type +'a t
>
>> The type of maps from type key to type 'a .
>
> val empty : 'a t
>
>> The empty map.
>
> val is_empty : 'a t -> bool
>
>> Test whether a map is empty or not.
>
> val mem : key -> 'a t -> bool
>
>> mem x m returns true if m contains a binding for x, and false otherwise.
>
> val add : key -> 'a -> 'a t -> 'a t

add x y m returns a map containing the same bindings as m, plus a binding of x to y. If x was already bound in m, its previous binding disappears.

val singleton : key -> 'a -> 'a t

singleton x y returns the one-element map that contains a binding y for x.
Since: 3.12.0

val remove : key -> 'a t -> 'a t

remove x m returns a map containing the same bindings as m, except for x which is unbound in the returned map.

val merge :
  (key -> 'a option -> 'b option -> 'c option) ->
  'a t -> 'b t -> 'c t

merge f m1 m2 computes a map whose keys is a subset of keys of m1 and of m2 The presence of each such binding, and the corresponding value, is determined with the function f .
Since: 3.12.0

val compare : ('a -> 'a -> int) -> 'a t -> 'a t -> int

Total ordering between maps. The rst argument is a total ordering used to compare data associated with equal keys in the two maps.

val equal : ('a -> 'a -> bool) -> 'a t -> 'a t -> bool

equal cmp m1 m2 tests whether the maps m1 and m2 are equal, that is, contain equal keys and associate them with equal data. cmp is the equality predicate used to compare the data associated with the keys.

val iter : (key -> 'a -> unit) -> 'a t -> unit

iter f m applies f to all bindings in map m f receives the key as rst argument, and the associated value as second argument. The bindings are passed to f in increasing order with respect to the ordering over the type of the keys.

val fold : (key -> 'a -> 'b -> 'b) -> 'a t -> 'b -> 'b

fold f m a computes (f kN dN ... (f k1 d1 a)...) , where k1 ... kN are the keys of all bindings in m (in increasing order), and d1 ... dN are the associated data.

val for_all : (key -> 'a -> bool) -> 'a t -> bool

for_all p m checks if all the bindings of the map satisfy the predicate p.
Since: 3.12.0

val exists : (key -> 'a -> bool) -> 'a t -> bool

exists p m checks if at least one binding of the map satisfy the predicate p.
Since: 3.12.0

val filter : (key -> 'a -> bool) -> 'a t -> 'a t

filter p m returns the map with all the bindings in m that satisfy predicate p.
Since: 3.12.0

val partition : (key -> 'a -> bool) -> 'a t -> 'a t * 'a t

partition p m returns a pair of maps (m1, m2), where m1 contains all the bindings of
s that satisfy the predicate p, and m2 is the map with all the bindings of s that do not
satisfy p.
Since: 3.12.0

val cardinal : 'a t -> int

Return the number of bindings of a map.
Since: 3.12.0

val bindings : 'a t -> (key * 'a) list

Return the list of all bindings of the given map. The returned list is sorted in
increasing order with respect to the ordering Ord.compare, where Ord is the argument
given to Map.Make [23].
Since: 3.12.0

val min_binding : 'a t -> key * 'a

Return the smallest binding of the given map (with respect to the Ord.compare
ordering), or raise Not_found if the map is empty.
Since: 3.12.0

val max_binding : 'a t -> key * 'a

Same as Map.S.min_binding [23], but returns the largest binding of the given map.
Since: 3.12.0

val choose : 'a t -> key * 'a

Return one binding of the given map, or raise Not_found if the map is empty. Which
binding is chosen is unspecified, but equal bindings will be chosen for equal maps.
Since: 3.12.0

val split : key -> 'a t -> 'a t * 'a option * 'a t

split x m returns a triple (l, data, r), where l is the map with all the bindings of m
whose key is strictly less than x; r is the map with all the bindings of m whose key is
strictly greater than x; data is None if m contains no binding for x, or Some v if m binds
v to x.
Since: 3.12.0

val find : key -> 'a t -> 'a

> find x m returns the current binding of x in m, or raises Not_found if no such binding exists.

val map : ('a -> 'b) -> 'a t -> 'b t

> map f m returns a map with same domain as m, where the associated value a of all bindings of m has been replaced by the result of the application of f to a. The bindings are passed to f in increasing order with respect to the ordering over the type of the keys.

val mapi : (key -> 'a -> 'b) -> 'a t -> 'b t

> Same as Map.S.map [23], but the function receives as arguments both the key and the associated value for each binding of the map.

end

> Output signature of the functor Map.Make [23].

module Make :
  functor (Ord : OrderedType) -> S with type key = Ord.t
> Functor building an implementation of the map structure given a totally ordered type.

24 Module Marshal : Marshaling of data structures.

This module provides functions to encode arbitrary data structures as sequences of bytes, which can then be written on a file or sent over a pipe or network connection. The bytes can then be read back later, possibly in another process, and decoded back into a data structure. The format for the byte sequences is compatible across all machines for a given version of Objective Caml.

   Warning: marshaling is currently not type-safe. The type of marshaled data is not transmitted along the value of the data, making it impossible to check that the data read back possesses the type expected by the context. In particular, the result type of the Marshal.from_* functions is given as 'a , but this is misleading: the returned Caml value does not possess type 'a for all 'a ; it has one, unique type which cannot be determined at compile-type. The programmer should explicitly give the expected type of the returned value, using the following syntax:

- (Marshal.from_channel chan : type) . Anything can happen at run-time if the object in the file does not belong to the given type.

   The representation of marshaled values is not human-readable, and uses bytes that are not printable characters. Therefore, input and output channels used in conjunction with Marshal.to_channel and Marshal.from_channel must be opened in binary mode, using e.g. open_out_bin or open_in_bin ; channels opened in text mode will cause unmarshaling errors on platforms where text channels behave differently than binary channels, e.g. Windows.

type extern_flags =
  | No_sharing

Don't preserve sharing

| Closures

Send function closures

The ags to the Marshal.to_* functions below.

val to_channel : Pervasives.out_channel -> 'a -> extern_flags list -> unit

Marshal.to_channel chan v flags writes the representation of v on channel chan. The flags argument is a possibly empty list of ags that governs the marshaling behavior with respect to sharing and functional values.

If flags does not contain Marshal.No_sharing , circularities and sharing inside the value v are detected and preserved in the sequence of bytes produced. In particular, this guarantees that marshaling always terminates. Sharing between values marshaled by successive calls to Marshal.to_channel is not detected, though. If flags contains Marshal.No_sharing , sharing is ignored. This results in faster marshaling if v contains no shared substructures, but may cause slower marshaling and larger byte representations if v actually contains sharing, or even non-termination if v contains cycles.

If flags does not contain Marshal.Closures , marshaling fails when it encounters a functional value inside v: only pure data structures, containing neither functions nor objects, can safely be transmitted between di erent programs. If flags contains Marshal.Closures , functional values will be marshaled as a position in the code of the program. In this case, the output of marshaling can only be read back in processes that run exactly the same program, with exactly the same compiled code. (This is checked at un-marshaling time, using an MD5 digest of the code transmitted along with the code position.)

val to_string : 'a -> extern_flags list -> string

Marshal.to_string v flags returns a string containing the representation of v as a sequence of bytes. The flags argument has the same meaning as for Marshal.to_channel [24].

val to_buffer : string -> int -> int -> 'a -> extern_flags list -> int

Marshal.to_buffer buff ofs len v flags marshals the value v, storing its byte representation in the string buff , starting at character number ofs , and writing at most len characters. It returns the number of characters actually written to the string. If the byte representation of v does not t in len characters, the exception Failure is raised.

val from_channel : Pervasives.in_channel -> 'a

Marshal.from_channel chan reads from channel chan the byte representation of a structured value, as produced by one of the Marshal.to_* functions, and reconstructs and returns the corresponding value.

val from_string : string -> int -> 'a

Marshal.from_string buff ofs unmarshals a structured value like Marshal.from_channel [24] does, except that the byte representation is not read from a channel, but taken from the string buff , starting at position ofs .

val header_size : int

> The bytes representing a marshaled value are composed of a xed-size header and a variable-sized data part, whose size can be determined from the header. Marshal.header_size [24] is the size, in characters, of the header.Marshal.data_size [24] buff ofs is the size, in characters, of the data part, assuming a valid header is stored in buff starting at position ofs . Finally, Marshal.total_size [24] buff ofs is the total size, in characters, of the marshaled value. BothMarshal.data_size [24] and Marshal.total_size [24] raiseFailure if buff , ofs does not contain a valid header.

> To read the byte representation of a marshaled value into a string bu er, the program needs to read rst Marshal.header_size [24] characters into the bu er, then determine the length of the remainder of the representation usingMarshal.data_size [24], make sure the bu er is large enough to hold the remaining data, then read it, and nally call Marshal.from_string [24] to unmarshal the value.

val data_size : string -> int -> int
> SeeMarshal.header_size [24].

val total_size : string -> int -> int
> SeeMarshal.header_size [24].

25 Module MoreLabels : Extra labeled libraries.

This meta-module provides labelized version of the Hashtbl [16], Map[23] and Set[36] modules.
   They only di er by their labels. They are provided to help porting from previous versions of Objective Caml. The contents of this module are subject to change.

module Hashtbl :
  sig
      type ('a, 'b) t = ('a, 'b) Hashtbl.t
      val create : int -> ('a, 'b) t
      val clear : ('a, 'b) t -> unit

  end
```

26 Module Nativeint : Processor-native integers.

This module provides operations on the type nativeint of signed 32-bit integers (on 32-bit plat-
forms) or signed 64-bit integers (on 64-bit platforms). This integer type has exactly the same width
as that of a long integer type in the C compiler. All arithmetic operations over nativeint are
taken modulo 2^{32} or 2^{64} depending on the word size of the architecture.

Performance notice: values of type nativeint occupy more memory space than values of type
int , and arithmetic operations on nativeint are generally slower than those on int . Use nativeint
only when the application requires the extra bit of precision over the int type.

val zero : nativeint
    The native integer 0.

val one : nativeint
    The native integer 1.

val minus_one : nativeint
    The native integer -1.

val neg : nativeint -> nativeint
    Unary negation.

val add : nativeint -> nativeint -> nativeint
    Addition.

val sub : nativeint -> nativeint -> nativeint
    Subtraction.

val mul : nativeint -> nativeint -> nativeint
    Multiplication.

val div : nativeint -> nativeint -> nativeint
    Integer division. Raise Division_by_zero if the second argument is zero. This division
    rounds the real quotient of its arguments towards zero, as specified for Pervasives.(/) [30].

val rem : nativeint -> nativeint -> nativeint
    Integer remainder. If y is not zero, the result of Nativeint.rem x y satisfies the following
    properties: Nativeint.zero <= Nativeint.rem x y < Nativeint.abs y and x =
    Nativeint.add (Nativeint.mul (Nativeint.div x y) y) (Nativeint.rem x y) . If y =
    0, Nativeint.rem x y raises Division_by_zero .

val succ : nativeint -> nativeint
    Successor. Nativeint.succ x is Nativeint.add x Nativeint.one .

val pred : nativeint -> nativeint

Predecessor. `Nativeint.pred x` is `Nativeint.sub x Nativeint.one` .

val abs : nativeint -> nativeint

Return the absolute value of its argument.

val size : int

The size in bits of a native integer. This is equal to 32 on a 32-bit platform and to 64 on a 64-bit platform.

val max_int : nativeint

The greatest representable native integer, either 2^{31} - 1 on a 32-bit platform, or 2^{63} - 1 on a 64-bit platform.

val min_int : nativeint

The greatest representable native integer, either -2^{31} on a 32-bit platform, or -2^{63} on a 64-bit platform.

val logand : nativeint -> nativeint -> nativeint

Bitwise logical and.

val logor : nativeint -> nativeint -> nativeint

Bitwise logical or.

val logxor : nativeint -> nativeint -> nativeint

Bitwise logical exclusive or.

val lognot : nativeint -> nativeint

Bitwise logical negation

val shift_left : nativeint -> int -> nativeint

`Nativeint.shift_left x y` shifts x to the left by y bits. The result is unspecified if y < 0 or y >= `bitsize` , where `bitsize` is 32 on a 32-bit platform and 64 on a 64-bit platform.

val shift_right : nativeint -> int -> nativeint

`Nativeint.shift_right x y` shifts x to the right by y bits. This is an arithmetic shift: the sign bit of x is replicated and inserted in the vacated bits. The result is unspecified if y < 0 or y >= `bitsize` .

val shift_right_logical : nativeint -> int -> nativeint

`Nativeint.shift_right_logical x y` shifts x to the right by y bits. This is a logical shift: zeroes are inserted in the vacated bits regardless of the sign of x. The result is unspecified if y < 0 or y >= `bitsize` .

val of_int : int -> nativeint

Convert the given integer (type int) to a native integer (type nativeint).

val to_int : nativeint -> int

> Convert the given native integer (type nativeint) to an integer (type int). The high-order bit is lost during the conversion.

val of_float : float -> nativeint

> Convert the given oating-point number to a native integer, discarding the fractional part (truncate towards 0). The result of the conversion is unde ned if, after truncation, the number is outside the range [Nativeint.min_int [26], Nativeint.max_int [26]].

val to_float : nativeint -> float

> Convert the given native integer to a oating-point number.

val of_int32 : int32 -> nativeint

> Convert the given 32-bit integer (type int32) to a native integer.

val to_int32 : nativeint -> int32

> Convert the given native integer to a 32-bit integer (type int32). On 64-bit platforms, the 64-bit native integer is taken modulo 2^{32}, i.e. the top 32 bits are lost. On 32-bit platforms, the conversion is exact.

val of_string : string -> nativeint

> Convert the given string to a native integer. The string is read in decimal (by default) or in hexadecimal, octal or binary if the string begins with 0x, 0o or 0b respectively. Raise Failure "int_of_string" if the given string is not a valid representation of an integer, or if the integer represented exceeds the range of integers representable in type nativeint .

val to_string : nativeint -> string

> Return the string representation of its argument, in decimal.

type t = nativeint

> An alias for the type of native integers.

val compare : t -> t -> int

> The comparison function for native integers, with the same speci cation as Pervasives.compare [30]. Along with the type t , this function compare allows the module Nativeint to be passed as argument to the functors Set.Make [36] and Map.Make [23].

27   Module Obj : Operations on internal representations of values.

Not for the casual user.

type t
val repr : 'a -> t

```
val obj : t -> 'a

val magic : 'a -> 'b

val is_block : t -> bool

val is_int : t -> bool

val tag : t -> int

val set_tag : t -> int -> unit

val size : t -> int

val field : t -> int -> t

val set_field : t -> int -> t -> unit

val double_field : t -> int -> float

val set_double_field : t -> int -> float -> unit

val new_block : int -> int -> t

val dup : t -> t

val truncate : t -> int -> unit

val add_offset : t -> Int32.t -> t

val lazy_tag : int

val closure_tag : int

val object_tag : int

val infix_tag : int

val forward_tag : int

val no_scan_tag : int

val abstract_tag : int

val string_tag : int

val double_tag : int

val double_array_tag : int

val custom_tag : int

val final_tag : int

val int_tag : int

val out_of_heap_tag : int

val unaligned_tag : int
```
   The following two functions are deprecated. Use module Marshal[24] instead.
```
val marshal : t -> string

val unmarshal : string -> int -> t * int
```

28   Module Oo: Operations on objects

```
val copy : (< .. > as 'a) -> 'a
```

Oo.copy o returns a copy of object o, that is a fresh object with the same methods and instance variables as o.

val id : < .. > -> int

Return an integer identifying this object, unique for the current execution of the program.

29 Module Parsing : The run-time library for parsers generated by ocamlyacc.

val symbol_start : unit -> int

symbol_start and Parsing.symbol_end [29] are to be called in the action part of a grammar rule only. They return the o set of the string that matches the left-hand side of the rule: symbol_start() returns the o set of the rst character; symbol_end() returns the o set after the last character. The rst character in a le is at o set 0.

val symbol_end : unit -> int

See Parsing.symbol_start [29].

val rhs_start : int -> int

Same as Parsing.symbol_start [29] and Parsing.symbol_end [29], but return the o set of the string matching the nth item on the right-hand side of the rule, where n is the integer parameter to rhs_start and rhs_end. n is 1 for the leftmost item.

val rhs_end : int -> int

See Parsing.rhs_start [29].

val symbol_start_pos : unit -> Lexing.position

Same as symbol_start, but return a position instead of an o set.

val symbol_end_pos : unit -> Lexing.position

Same as symbol_end, but return a position instead of an o set.

val rhs_start_pos : int -> Lexing.position

Same as rhs_start, but return a position instead of an o set.

val rhs_end_pos : int -> Lexing.position

Same as rhs_end, but return a position instead of an o set.

val clear_parser : unit -> unit

Empty the parser stack. Call it just after a parsing function has returned, to remove all pointers from the parser stack to structures that were built by semantic actions during parsing. This is optional, but lowers the memory requirements of the programs.

exception Parse_error

> Raised when a parser encounters a syntax error. Can also be raised from the action part of a grammar rule, to initiate error recovery.

val set_trace : bool -> bool

> Control debugging support for ocamlyacc-generated parsers. After Parsing.set_trace true , the pushdown automaton that executes the parsers prints a trace of its actions (reading a token, shifting a state, reducing by a rule) on standard output. Parsing.set_trace false turns this debugging trace o . The boolean returned is the previous state of the trace ag.
>
> Since: 3.11.0

30 Module Pervasives : The initially opened module.

This module provides the basic operations over the built-in types (numbers, booleans, strings, exceptions, references, lists, arrays, input-output channels, . .).

This module is automatically opened at the beginning of each compilation. All components of this module can therefore be referred by their short name, without pre xing them by Pervasives .

Exceptions

val raise : exn -> 'a

> Raise the given exception value

val invalid_arg : string -> 'a

> Raise exception Invalid_argument with the given string.

val failwith : string -> 'a

> Raise exception Failure with the given string.

exception Exit

> The Exit exception is not raised by any library function. It is provided for use in your programs.

Comparisons

val (=) : 'a -> 'a -> bool

> e1 = e2 tests for structural equality of e1 and e2. Mutable structures (e.g. references and arrays) are equal if and only if their current contents are structurally equal, even if the two mutable objects are not the same physical object. Equality between functional values raises Invalid_argument . Equality between cyclic data structures may not terminate.

val (<>) : 'a -> 'a -> bool

> Negation of Pervasives.(=) [30].

val (<) : 'a -> 'a -> bool

See Pervasives.(>=) [30].

val (>) : 'a -> 'a -> bool

See Pervasives.(>=) [30].

val (<=) : 'a -> 'a -> bool

See Pervasives.(>=) [30].

val (>=) : 'a -> 'a -> bool

Structural ordering functions. These functions coincide with the usual orderings over integers, characters, strings and oating-point numbers, and extend them to a total ordering over all types. The ordering is compatible with (=) . As in the case of (=) , mutable structures are compared by contents. Comparison between functional values raises Invalid_argument . Comparison between cyclic structures may not terminate.

val compare : 'a -> 'a -> int

compare x y returns 0 if x is equal to y, a negative integer if x is less than y, and a positive integer if x is greater than y. The ordering implemented by compare is compatible with the comparison predicates =, < and > de ned above, with one di erence on the treatment of the oat value Pervasives.nan [30]. Namely, the comparison predicates treat nan as di erent from any other oat value, including itself; while compare treats nan as equal to itself and less than any other oat value. This treatment of nan ensures that compare de nes a total ordering relation.

compare applied to functional values may raise Invalid_argument . compare applied to cyclic structures may not terminate.

The compare function can be used as the comparison function required by the Set.Make [36] and Map.Make [23] functors, as well as the List.sort [21] and Array.sort [2] functions.

val min : 'a -> 'a -> 'a

Return the smaller of the two arguments. The result is unspeci ed if one of the arguments contains the oat value nan.

val max : 'a -> 'a -> 'a

Return the greater of the two arguments. The result is unspeci ed if one of the arguments contains the oat value nan.

val (==) : 'a -> 'a -> bool

e1 == e2 tests for physical equality of e1 and e2. On mutable types such as references, arrays, strings, records with mutable elds and objects with mutable instance variables, e1 == e2 is true if and only if physical modi cation of e1 also a ects e2. On non-mutable types, the behavior of (==) is implementation-dependent; however, it is guaranteed that e1 == e2 implies compare e1 e2 = 0

val (!=) : 'a -> 'a -> bool

75

Negation of Pervasives.(==) [30].

Boolean operations

val not : bool -> bool

The boolean negation.

val (&&) : bool -> bool -> bool

The boolean and . Evaluation is sequential, left-to-right: in e1 && e2, e1 is evaluated rst, and if it returns false , e2 is not evaluated at all.

val (&) : bool -> bool -> bool

Deprecated. Pervasives.(&&) [30] should be used instead.

val (||) : bool -> bool -> bool

The boolean or . Evaluation is sequential, left-to-right: in e1 || e2 , e1 is evaluated rst, and if it returns true , e2 is not evaluated at all.

val (or) : bool -> bool -> bool

Deprecated. Pervasives.(||) [30] should be used instead.

Integer arithmetic

Integers are 31 bits wide (or 63 bits on 64-bit processors). All operations are taken modulo 2^{31} (or 2^{63}). They do not fail on over ow.

val (~-) : int -> int

Unary negation. You can also write- e instead of - e .

val (~+) : int -> int

Unary addition. You can also write + e instead of + e .

Since: 3.12.0

val succ : int -> int

succ x is x + 1.

val pred : int -> int

pred x is x - 1 .

val (+) : int -> int -> int

Integer addition.

val (-) : int -> int -> int

Integer subtraction.

val (*) : int -> int -> int

Integer multiplication.

val (/) : int -> int -> int

    Integer division. Raise Division_by_zero if the second argument is 0. Integer division rounds the real quotient of its arguments towards zero. More precisely, if $x >= 0$ and $y > 0$, x / y is the greatest integer less than or equal to the real quotient of x by y. Moreover, $(- x) / y = x / (- y) = - (x / y)$.

val (mod) : int -> int -> int

    Integer remainder. If y is not zero, the result of x mod y satisﬁes the following properties: $x = (x / y) * y + x \bmod y$ and $abs(x \bmod y) <= abs(y) - 1$. If $y = 0$, x mod y raises Division_by_zero . Note that x mod y is negative only if $x < 0$. Raise Division_by_zero if y is zero.

val abs : int -> int

    Return the absolute value of the argument. Note that this may be negative if the argument is min_int .

val max_int : int

    The greatest representable integer.

val min_int : int

    The smallest representable integer.

    Bitwise operations

val (land) : int -> int -> int

    Bitwise logical and.

val (lor) : int -> int -> int

    Bitwise logical or.

val (lxor) : int -> int -> int

    Bitwise logical exclusive or.

val lnot : int -> int

    Bitwise logical negation.

val (lsl) : int -> int -> int

    n lsl m shifts n to the left by m bits. The result is unspeciﬁed if $m < 0$ or $m >= bitsize$, where bitsize is 32 on a 32-bit platform and 64 on a 64-bit platform.

val (lsr) : int -> int -> int

    n lsr m shifts n to the right by m bits. This is a logical shift: zeroes are inserted regardless of the sign of n. The result is unspeciﬁed if $m < 0$ or $m >= bitsize$.

val (asr) : int -> int -> int

n asr m shifts n to the right by m bits. This is an arithmetic shift: the sign bit of n is replicated. The result is unspeci ed if m < 0 or m >= bitsize .

Floating-point arithmetic

Caml's oating-point numbers follow the IEEE 754 standard, using double precision (64 bits) numbers. Floating-point operations never raise an exception on over ow, under ow, division by zero, etc. Instead, special IEEE numbers are returned as appropriate, such as infinity for 1.0 /. 0.0 , neg_infinity for -1.0 /. 0.0 , and nan (not a number) for 0.0 /. 0.0 . These special numbers then propagate through oating-point computations as expected: for instance, 1.0 /. infinity is 0.0 , and any arithmetic operation with nan as argument returns nan as result.

val (~-.) : float -> float

Unary negation. You can also write -. e instead of -. e .

val (~+.) : float -> float

Unary addition. You can also write +. e instead of +. e .

Since: 3.12.0

val (+.) : float -> float -> float

Floating-point addition

val (-.) : float -> float -> float

Floating-point subtraction

val (*.) : float -> float -> float

Floating-point multiplication

val (/.) : float -> float -> float

Floating-point division.

val (**) : float -> float -> float

Exponentiation.

val sqrt : float -> float

Square root.

val exp : float -> float

Exponential.

val log : float -> float

Natural logarithm.

val log10 : float -> float

Base 10 logarithm.

val expm1 : float -> float

expm1 x computes exp x -. 1.0 , giving numerically-accurate results even if x is close to 0.0 .

Since: 3.12.0

val log1p : float -> float

log1p x computes log(1.0 +. x) (natural logarithm), giving numerically-accurate results even if x is close to 0.0 .

Since: 3.12.0

val cos : float -> float

Cosine. Argument is in radians.

val sin : float -> float

Sine. Argument is in radians.

val tan : float -> float

Tangent. Argument is in radians.

val acos : float -> float

Arc cosine. The argument must fall within the range [-1.0, 1.0] . Result is in radians and is between 0.0 and pi .

val asin : float -> float

Arc sine. The argument must fall within the range [-1.0, 1.0] . Result is in radians and is between -pi/2 and pi/2 .

val atan : float -> float

Arc tangent. Result is in radians and is between -pi/2 and pi/2 .

val atan2 : float -> float -> float

atan2 y x returns the arc tangent of y /. x . The signs of x and y are used to determine the quadrant of the result. Result is in radians and is between -pi and pi .

val cosh : float -> float

Hyperbolic cosine. Argument is in radians.

val sinh : float -> float

Hyperbolic sine. Argument is in radians.

val tanh : float -> float

Hyperbolic tangent. Argument is in radians.

val ceil : float -> float

Round above to an integer value. ceil f returns the least integer value greater than or equal to f . The result is returned as a oat.

79

val floor : float -> float

Round below to an integer value. `floor f` returns the greatest integer value less than or equal to `f`. The result is returned as a float.

val abs_float : float -> float

`abs_float f` returns the absolute value of `f`.

val mod_float : float -> float -> float

`mod_float a b` returns the remainder of `a` with respect to `b`. The returned value is `a -. n *. b`, where `n` is the quotient `a /. b` rounded towards zero to an integer.

val frexp : float -> float * int

`frexp f` returns the pair of the significant and the exponent of `f`. When `f` is zero, the significant `x` and the exponent `n` of `f` are equal to zero. When `f` is non-zero, they are defined by `f = x *. 2 ** n` and `0.5 <= x < 1.0`.

val ldexp : float -> int -> float

`ldexp x n` returns `x *. 2 ** n`.

val modf : float -> float * float

`modf f` returns the pair of the fractional and integral part of `f`.

val float : int -> float

Same as `Pervasives.float_of_int` [30].

val float_of_int : int -> float

Convert an integer to floating-point.

val truncate : float -> int

Same as `Pervasives.int_of_float` [30].

val int_of_float : float -> int

Truncate the given floating-point number to an integer. The result is unspecified if the argument is `nan` or falls outside the range of representable integers.

val infinity : float

Positive infinity.

val neg_infinity : float

Negative infinity.

val nan : float

A special floating-point value denoting the result of an undefined operation such as `0.0 /. 0.0`. Stands for 'not a number'. Any floating-point operation with `nan` as argument returns `nan` as result. As for floating-point comparisons, `=`, `<`, `<=`, `>` and `>=` return `false` and `<>` returns `true` if one or both of their arguments is `nan`.

val max_float : float

    The largest positive nite value of type float .

val min_float : float

    The smallest positive, non-zero, non-denormalized value of type float .

val epsilon_float : float

    The di erence between 1.0 and the smallest exactly representable oating-point number greater than 1.0 .

type fpclass =
  | FP_normal

        Normal number, none of the below

  | FP_subnormal

        Number very close to 0.0, has reduced precision

  | FP_zero

        Number is 0.0 or -0.0

  | FP_infinite

        Number is positive or negative in nity

  | FP_nan

        Not a number: result of an unde ned operation

    The ve classes of oating-point numbers, as determined by the Pervasives.classify_float [30] function.

val classify_float : float -> fpclass

    Return the class of the given oating-point number: normal, subnormal, zero, in nite, or not a number.

    String operations
    More string operations are provided in module String [41].

val (^) : string -> string -> string

    String concatenation.

    Character operations
    More character operations are provided in module Char [9].

val int_of_char : char -> int

    Return the ASCII code of the argument.

val char_of_int : int -> char

    Return the character with the given ASCII code. Raise Invalid_argument "char_of_int" if the argument is outside the range 0 255.

Unit operations

val ignore : 'a -> unit

Discard the value of its argument and return () . For instance, ignore(f x) discards the result of the side-e ecting function f . It is equivalent to f x; () , except that the latter may generate a compiler warning; writing ignore(f x) instead avoids the warning.

String conversion functions

val string_of_bool : bool -> string

Return the string representation of a boolean.

val bool_of_string : string -> bool

Convert the given string to a boolean. Raise Invalid_argument "bool_of_string" if the string is not "true" or "false" .

val string_of_int : int -> string

Return the string representation of an integer, in decimal.

val int_of_string : string -> int

Convert the given string to an integer. The string is read in decimal (by default) or in hexadecimal (if it begins with 0x or 0X), octal (if it begins with 0o or 0O), or binary (if it begins with 0b or 0B). Raise Failure "int_of_string" if the given string is not a valid representation of an integer, or if the integer represented exceeds the range of integers representable in type int .

val string_of_float : float -> string

Return the string representation of a oating-point number.

val float_of_string : string -> float

Convert the given string to a oat. Raise Failure "float_of_string" if the given string is not a valid representation of a oat.

Pair operations

val fst : 'a * 'b -> 'a

Return the rst component of a pair.

val snd : 'a * 'b -> 'b

Return the second component of a pair.

List operations

More list operations are provided in module List [21].

val (@) : 'a list -> 'a list -> 'a list

List concatenation.

Input/output

type in_channel

82

The type of input channel.

type out_channel

The type of output channel.

val stdin : in_channel

The standard input for the process.

val stdout : out_channel

The standard output for the process.

val stderr : out_channel

The standard error output for the process.

Output functions on standard output

val print_char : char -> unit

Print a character on standard output.

val print_string : string -> unit

Print a string on standard output.

val print_int : int -> unit

Print an integer, in decimal, on standard output.

val print_float : float -> unit

Print a oating-point number, in decimal, on standard output.

val print_endline : string -> unit

Print a string, followed by a newline character, on standard output and ush standard
output.

val print_newline : unit -> unit

Print a newline character on standard output, and ush standard output. This can be used
to simulate line bu ering of standard output.

Output functions on standard error

val prerr_char : char -> unit

Print a character on standard error.

val prerr_string : string -> unit

Print a string on standard error.

val prerr_int : int -> unit

Print an integer, in decimal, on standard error.

val prerr_float : float -> unit

    Print a oating-point number, in decimal, on standard error.

val prerr_endline : string -> unit

    Print a string, followed by a newline character on standard error and ush standard error.

val prerr_newline : unit -> unit

    Print a newline character on standard error, and ush standard error.

  Input functions on standard input

val read_line : unit -> string

    Flush standard output, then read characters from standard input until a newline character is encountered. Return the string of all characters read, without the newline character at the end.

val read_int : unit -> int

    Flush standard output, then read one line from standard input and convert it to an integer. Raise Failure "int_of_string" if the line read is not a valid representation of an integer.

val read_float : unit -> float

    Flush standard output, then read one line from standard input and convert it to a oating-point number. The result is unspeci ed if the line read is not a valid representation of a oating-point number.

  General output functions

type open_flag =
  | Open_rdonly

      open for reading.

  | Open_wronly

      open for writing.

  | Open_append

      open for appending: always write at end of le.

  | Open_creat

      create the le if it does not exist.

  | Open_trunc

      empty the le if it already exists.

  | Open_excl

      fail if Open_creat and the le already exists.

  | Open_binary

      open in binary mode (no conversion).

  | Open_text

open in text mode (may perform conversions).

| Open_nonblock

open in non-blocking mode.

Opening modes for Pervasives.open_out_gen [30] and Pervasives.open_in_gen [30].

val open_out : string -> out_channel

Open the named le for writing, and return a new output channel on that le, positionned
at the beginning of the le. The le is truncated to zero length if it already exists. It is
created if it does not already exists. Raise Sys_error if the le could not be opened.

val open_out_bin : string -> out_channel

Same as Pervasives.open_out [30], but the le is opened in binary mode, so that no
translation takes place during writes. On operating systems that do not distinguish between
text mode and binary mode, this function behaves like Pervasives.open_out [30].

val open_out_gen : open_flag list -> int -> string -> out_channel

open_out_gen mode perm filename opens the named le for writing, as described above.
The extra argument mode specify the opening mode. The extra argument perm speci es the
 le permissions, in case the le must be created. Pervasives.open_out [30] and
Pervasives.open_out_bin [30] are special cases of this function.

val flush : out_channel -> unit

Flush the bu er associated with the given output channel, performing all pending writes on
that channel. Interactive programs must be careful about ushing standard output and
standard error at the right time.

val flush_all : unit -> unit

Flush all open output channels; ignore errors.

val output_char : out_channel -> char -> unit

Write the character on the given output channel.

val output_string : out_channel -> string -> unit

Write the string on the given output channel.

val output : out_channel -> string -> int -> int -> unit

output oc buf pos len writes len characters from string buf , starting at o set pos, to the
given output channel oc. Raise Invalid_argument "output" if pos and len do not
designate a valid substring of buf .

val output_byte : out_channel -> int -> unit

Write one 8-bit integer (as the single character with that code) on the given output channel.
The given integer is taken modulo 256.

val output_binary_int : out_channel -> int -> unit

Write one integer in binary format (4 bytes, big-endian) on the given output channel. The given integer is taken modulo 2^{32}. The only reliable way to read it back is through the Pervasives.input_binary_int [30] function. The format is compatible across all machines for a given version of Objective Caml.

val output_value : out_channel -> 'a -> unit

Write the representation of a structured value of any type to a channel. Circularities and sharing inside the value are detected and preserved. The object can be read back, by the function Pervasives.input_value [30]. See the description of module Marshal[24] for more information. Pervasives.output_value [30] is equivalent to Marshal.to_channel [24] with an empty list of ags.

val seek_out : out_channel -> int -> unit

seek_out chan pos sets the current writing position to pos for channel chan. This works only for regular les. On les of other kinds (such as terminals, pipes and sockets), the behavior is unspeci ed.

val pos_out : out_channel -> int

Return the current writing position for the given channel. Does not work on channels opened with the Open_append ag (returns unspeci ed results).

val out_channel_length : out_channel -> int

Return the size (number of characters) of the regular le on which the given channel is opened. If the channel is opened on a le that is not a regular le, the result is meaningless.

val close_out : out_channel -> unit

Close the given channel, ushing all bu ered write operations. Output functions raise a Sys_error exception when they are applied to a closed output channel, except close_out and flush, which do nothing when applied to an already closed channel. Note that close_out may raise Sys_error if the operating system signals an error when ushing or closing.

val close_out_noerr : out_channel -> unit

Same as close_out, but ignore all errors.

val set_binary_mode_out : out_channel -> bool -> unit

set_binary_mode_out oc true sets the channel oc to binary mode: no translations take place during output. set_binary_mode_out oc false sets the channel oc to text mode: depending on the operating system, some translations may take place during output. For instance, under Windows, end-of-lines will be translated from \n to \r\n. This function has no e ect under operating systems that do not distinguish between text mode and binary mode.

General input functions

val open_in : string -> in_channel

Open the named le for reading, and return a new input channel on that le, positionned at the beginning of the le. Raise Sys_error if the le could not be opened.

val open_in_bin : string -> in_channel

Same as Pervasives.open_in [30], but the le is opened in binary mode, so that no translation takes place during reads. On operating systems that do not distinguish between text mode and binary mode, this function behaves like Pervasives.open_in [30].

val open_in_gen : open_flag list -> int -> string -> in_channel

open_in_gen mode perm filename opens the named le for reading, as described above. The extra arguments mode and perm specify the opening mode and le permissions. Pervasives.open_in [30] and Pervasives.open_in_bin [30] are special cases of this function.

val input_char : in_channel -> char

Read one character from the given input channel. Raise End_of_file if there are no more characters to read.

val input_line : in_channel -> string

Read characters from the given input channel, until a newline character is encountered. Return the string of all characters read, without the newline character at the end. Raise End_of_file if the end of the le is reached at the beginning of line.

val input : in_channel -> string -> int -> int -> int

input ic buf pos len reads up to len characters from the given channel ic , storing them in string buf , starting at character number pos. It returns the actual number of characters read, between 0 and len (inclusive). A return value of 0 means that the end of le was reached. A return value between 0 and len exclusive means that not all requested len characters were read, either because no more characters were available at that time, or because the implementation found it convenient to do a partial read. input must be called again to read the remaining characters, if desired. (See also Pervasives.really_input [30] for reading exactly len characters.) Exception Invalid_argument "input" is raised if pos and len do not designate a valid substring of buf .

val really_input : in_channel -> string -> int -> int -> unit

really_input ic buf pos len reads len characters from channel ic , storing them in string buf , starting at character number pos. Raise End_of_file if the end of le is reached before len characters have been read. Raise Invalid_argument "really_input" if pos and len do not designate a valid substring of buf .

val input_byte : in_channel -> int

Same as Pervasives.input_char [30], but return the 8-bit integer representing the character. Raise End_of_file if an end of le was reached.

val input_binary_int : in_channel -> int

Read an integer encoded in binary format (4 bytes, big-endian) from the given input channel. See Pervasives.output_binary_int [30]. Raise End_of_file if an end of le was reached while reading the integer.

val input_value : in_channel -> 'a

Read the representation of a structured value, as produced by Pervasives.output_value [30], and return the corresponding value. This function is identical to Marshal.from_channel [24]; see the description of module Marshal[24] for more information, in particular concerning the lack of type safety.

val seek_in : in_channel -> int -> unit

seek_in chan pos sets the current reading position to pos for channel chan. This works only for regular les. On les of other kinds, the behavior is unspeci ed.

val pos_in : in_channel -> int

Return the current reading position for the given channel.

val in_channel_length : in_channel -> int

Return the size (number of characters) of the regular le on which the given channel is opened. If the channel is opened on a le that is not a regular le, the result is meaningless. The returned size does not take into account the end-of-line translations that can be performed when reading from a channel opened in text mode.

val close_in : in_channel -> unit

Close the given channel. Input functions raise a Sys_error exception when they are applied to a closed input channel, except close_in, which does nothing when applied to an already closed channel. Note that close_in may raise Sys_error if the operating system signals an error.

val close_in_noerr : in_channel -> unit

Same as close_in, but ignore all errors.

val set_binary_mode_in : in_channel -> bool -> unit

set_binary_mode_in ic true sets the channel ic to binary mode: no translations take place during input. set_binary_mode_out ic false sets the channel ic to text mode: depending on the operating system, some translations may take place during input. For instance, under Windows, end-of-lines will be translated from \r\n to \n. This function has no e ect under operating systems that do not distinguish between text mode and binary mode.

Operations on large les

module LargeFile :
  sig

88

val seek_out : Pervasives.out_channel -> int64 -> unit

val pos_out : Pervasives.out_channel -> int64

val out_channel_length : Pervasives.out_channel -> int64

val seek_in : Pervasives.in_channel -> int64 -> unit

val pos_in : Pervasives.in_channel -> int64

val in_channel_length : Pervasives.in_channel -> int64

end

Operations on large les. This sub-module provides 64-bit variants of the channel functions that manipulate le positions and le sizes. By representing positions and sizes by 64-bit integers (type int64) instead of regular integers (type int), these alternate functions allow operating on les whose sizes are greater than max_int.

References

```
type 'a ref = {
  mutable contents : 'a ;
}
```

The type of references (mutable indirection cells) containing a value of type 'a .

val ref : 'a -> 'a ref

Return a fresh reference containing the given value.

val (!) : 'a ref -> 'a

!r returns the current contents of reference r . Equivalent to fun r -> r.contents .

val (:=) : 'a ref -> 'a -> unit

r := a stores the value of a in reference r . Equivalent to fun r v -> r.contents <- v .

val incr : int ref -> unit

Increment the integer contained in the given reference. Equivalent to fun r -> r := succ !r .

val decr : int ref -> unit

Decrement the integer contained in the given reference. Equivalent to fun r -> r := pred !r .

Operations on format strings

Format strings are used to read and print data using formatted input functions in module Scanf[35] and formatted output in modules Printf [32] and Format[13].

type ('a, 'b, 'c, 'd) format4 = ('a, 'b, 'c, 'c, 'c, 'd) format6

Format strings have a general and highly polymorphic type ('a, 'b, 'c, 'd, 'e, 'f) format6 . Type format6 is built in. The two simpli ed types, format and format4 below are included for backward compatibility with earlier releases of Objective Caml. 'a is the type of the parameters of the format, 'b is the type of the rst argument given to %a and %t printing

89

functions, 'c is the type of the argument transmitted to the rst argument of "kprintf"-style functions, 'd is the result type for the "scanf"-style functions, 'e is the type of the receiver function for the "scanf"-style functions, 'f is the result type for the "printf"-style function.

type ('a, 'b, 'c) format = ('a, 'b, 'c, 'c) format4

val string_of_format : ('a, 'b, 'c, 'd, 'e, 'f) format6 -> string

Converts a format string into a string.

val format_of_string :
    ('a, 'b, 'c, 'd, 'e, 'f) format6 -> ('a, 'b, 'c, 'd, 'e, 'f) format6

format_of_string s returns a format string read from the string literal s.

val (^^) :
    ('a, 'b, 'c, 'd, 'e, 'f) format6 ->
    ('f, 'b, 'c, 'e, 'g, 'h) format6 -> ('a, 'b, 'c, 'd, 'g, 'h) format6

f1 ^^f2 catenates formatsf1 and f2 . The result is a format that accepts arguments from f1 , then arguments from f2 .

Program termination

val exit : int -> 'a

Terminate the process, returning the given status code to the operating system: usually 0 to indicate no errors, and a small positive integer to indicate failure. All open output channels are ushed with ush_all. An implicit exit 0 is performed each time a program terminates normally. An implicit exit 2 is performed if the program terminates early because of an uncaught exception.

val at_exit : (unit -> unit) -> unit

Register the given function to be called at program termination time. The functions registered with at_exit will be called when the program executes Pervasives.exit [30], or terminates, either normally or because of an uncaught exception. The functions are called in last in, rst out order: the function most recently added with at_exit is called rst.

31 Module Printexc : Facilities for printing exceptions.

val to_string : exn -> string

Printexc.to_string e returns a string representation of the exception e.

val print : ('a -> 'b) -> 'a -> 'b

Printexc.print fn x applies fn to x and returns the result. If the evaluation of fn x raises any exception, the name of the exception is printed on standard error output, and the exception is raised again. The typical use is to catch and report exceptions that escape a function application.

val catch : ('a -> 'b) -> 'a -> 'b

> Printexc.catch fn x is similar to Printexc.print [31], but aborts the program with exit code 2 after printing the uncaught exception. This function is deprecated: the runtime system is now able to print uncaught exceptions as precisely as Printexc.catch does. Moreover, calling Printexc.catch makes it harder to track the location of the exception using the debugger or the stack backtrace facility. So, do not use Printexc.catch in new code.

val print_backtrace : Pervasives.out_channel -> unit

> Printexc.print_backtrace oc prints an exception backtrace on the output channel oc. The backtrace lists the program locations where the most-recently raised exception was raised and where it was propagated through function calls.
>
> Since: 3.11.0

val get_backtrace : unit -> string

> Printexc.get_backtrace () returns a string containing the same exception backtrace that Printexc.print_backtrace would print.
>
> Since: 3.11.0

val record_backtrace : bool -> unit

> Printexc.record_backtrace b turns recording of exception backtraces on (if b = true) or o (if b = false). Initially, backtraces are not recorded, unless the b ag is given to the program through the OCAMLRUNPARAM variable.
>
> Since: 3.11.0

val backtrace_status : unit -> bool

> Printexc.backtrace_status() returns true if exception backtraces are currently recorded, false if not.
>
> Since: 3.11.0

val register_printer : (exn -> string option) -> unit

> Printexc.register_printer fn registers fn as an exception printer. The printer should return None or raise an exception if it does not know how to convert the passed exception, and Some s with s the resulting string if it can convert the passed exception. Exceptions raised by the printer are ignored.
>
> When converting an exception into a string, the printers will be invoked in the reverse order of their registrations, until a printer returns a Some s value (if no such printer exists, the runtime will use a generic printer).
>
> Since: 3.11.2

32   Module Printf : Formatted output functions.

val fprintf :
  Pervasives.out_channel ->
  ('a, Pervasives.out_channel, unit) Pervasives.format -> 'a

> fprintf outchan format arg1 ... argN   formats the arguments arg1 to argN according
> to the format string format , and outputs the resulting string on the channel outchan.
>
> The format is a character string which contains two types of objects: plain characters, which
> are simply copied to the output channel, and conversion speci cations, each of which causes
> conversion and printing of arguments.
>
> Conversion speci cations have the following form:
>
> % [flags] [width] [.precision] type
>
> In short, a conversion speci cation consists in the % character, followed by optional modi ers
> and a type which is made of one or two characters. The types and their meanings are:
>
> * d, i , n, l , L, or N: convert an integer argument to signed decimal.
> * u: convert an integer argument to unsigned decimal.
> * x: convert an integer argument to unsigned hexadecimal, using lowercase letters.
> * X: convert an integer argument to unsigned hexadecimal, using uppercase letters.
> * o: convert an integer argument to unsigned octal.
> * s: insert a string argument.
> * S: insert a string argument in Caml syntax (double quotes, escapes).
> * c: insert a character argument.
> * C: insert a character argument in Caml syntax (single quotes, escapes).
> * f : convert a oating-point argument to decimal notation, in the style dddd.ddd.
> * F: convert a oating-point argument to Caml syntax (dddd. or dddd.ddd or d.ddd
>   e+-dd).
> * e or E: convert a oating-point argument to decimal notation, in the style d.ddd e+-dd
>   (mantissa and exponent).
> * g or G: convert a oating-point argument to decimal notation, in style f or e, E
>   (whichever is more compact).
> * B: convert a boolean argument to the string true or false
> * b: convert a boolean argument (for backward compatibility; do not use in new
>   programs).
> * ld , li , lu , lx , lX, lo : convert an int32 argument to the format speci ed by the second
>   letter (decimal, hexadecimal, etc).
> * nd, ni , nu, nx, nX, no: convert a nativeint   argument to the format speci ed by the
>   second letter.

- Ld, Li , Lu, Lx, LX, Lo: convert an int64 argument to the format specified by the second letter.
- a: user-defined printer. Takes two arguments and applies the first one to outchan (the current output channel) and to the second argument. The first argument must therefore have type out_channel -> 'b -> unit and the second 'b . The output produced by the function is inserted in the output of fprintf at the current point.
- t : same as %a but takes only one argument (with type out_channel -> unit) and apply it to outchan.
- { fmt %}: convert a format string argument. The argument must have the same type as the internal format string fmt .
- (fmt %): format string substitution. Takes a format string argument and substitutes it to the internal format string fmt to print following arguments. The argument must have the same type as the internal format string fmt .
- ! : take no argument and flush the output.
- % take no argument and output one % character.
- , : the no-op delimiter for conversion specifications.

The optional flags are:

- - : left-justify the output (default is right justification).
- 0: for numerical conversions, pad with zeroes instead of spaces.
- +: for numerical conversions, prefix number with a + sign if positive.
- space: for numerical conversions, prefix number with a space if positive.
- #: request an alternate formatting style for numbers.

The optional width is an integer indicating the minimal width of the result. For instance, %6d prints an integer, prefixing it with spaces to fill at least 6 characters.

The optional precision is a dot . followed by an integer indicating how many digits follow the decimal point in the %f, %e, and %E conversions. For instance, %.4f prints a float with 4 fractional digits.

The integer in a width or precision can also be specified as *, in which case an extra integer argument is taken to specify the corresponding width or precision . This integer argument precedes immediately the argument to print. For instance, %.*f prints a float with as many fractional digits as the value of the argument given before the float.

val printf : ('a, Pervasives.out_channel, unit) Pervasives.format -> 'a
    Same as Printf.fprintf [32], but output on stdout .

val eprintf : ('a, Pervasives.out_channel, unit) Pervasives.format -> 'a
    Same as Printf.fprintf [32], but output on stderr .

val ifprintf : 'a -> ('b, 'a, unit) Pervasives.format -> 'b

Same as `Printf.fprintf` [32], but does not print anything. Useful to ignore some material when conditionally printing.

Since: 3.10.0

val sprintf : ('a, unit, string) Pervasives.format -> 'a

Same as `Printf.fprintf` [32], but instead of printing on an output channel, return a string containing the result of formatting the arguments.

val bprintf : Buffer.t -> ('a, Buffer.t, unit) Pervasives.format -> 'a

Same as `Printf.fprintf` [32], but instead of printing on an output channel, append the formatted arguments to the given extensible bu er (see module `Buffer` [4]).

Formatted output functions with continuations.

val kfprintf :
  (Pervasives.out_channel -> 'a) ->
  Pervasives.out_channel ->
  ('b, Pervasives.out_channel, unit, 'a) Pervasives.format4 -> 'b

Same as `fprintf`, but instead of returning immediately, passes the out channel to its rst argument at the end of printing.

Since: 3.09.0

val ksprintf :
  (string -> 'a) -> ('b, unit, string, 'a) Pervasives.format4 -> 'b

Same as `sprintf` above, but instead of returning the string, passes it to the rst argument.

Since: 3.09.0

val kbprintf :
  (Buffer.t -> 'a) ->
  Buffer.t -> ('b, Buffer.t, unit, 'a) Pervasives.format4 -> 'b

Same as `bprintf`, but instead of returning immediately, passes the bu er to its rst argument at the end of printing.

Since: 3.10.0

Deprecated

val kprintf :
  (string -> 'a) -> ('b, unit, string, 'a) Pervasives.format4 -> 'b

A deprecated synonym for `ksprintf`.

33 Module Queue: First-in rst-out queues.

This module implements queues (FIFOs), with in-place modi cation.

type 'a t

The type of queues containing elements of type 'a .

exception Empty

    Raised when Queue.take [33] or Queue.peek [33] is applied to an empty queue.

val create : unit -> 'a t

    Return a new queue, initially empty.

val add : 'a -> 'a t -> unit

    add x q adds the element x at the end of the queue q.

val push : 'a -> 'a t -> unit

    push is a synonym for add.

val take : 'a t -> 'a

    take q removes and returns the first element in queue q, or raises Empty if the queue is empty.

val pop : 'a t -> 'a

    pop is a synonym for take .

val peek : 'a t -> 'a

    peek q returns the first element in queue q, without removing it from the queue, or raises Empty if the queue is empty.

val top : 'a t -> 'a

    top is a synonym for peek.

val clear : 'a t -> unit

    Discard all elements from a queue.

val copy : 'a t -> 'a t

    Return a copy of the given queue.

val is_empty : 'a t -> bool

    Return true if the given queue is empty, false otherwise.

val length : 'a t -> int

    Return the number of elements in a queue.

val iter : ('a -> unit) -> 'a t -> unit

    iter f q applies f in turn to all elements of q, from the least recently entered to the most recently entered. The queue itself is unchanged.

val fold : ('a -> 'b -> 'a) -> 'a -> 'b t -> 'a

fold f accu q is equivalent to List.fold_left f accu l , where l is the list of q's elements. The queue remains unchanged.

val transfer : 'a t -> 'a t -> unit

transfer q1 q2 adds all of q1's elements at the end of the queue q2, then clears q1. It is equivalent to the sequence iter (fun x -> add x q2) q1; clear q1 , but runs in constant time.

34 Module Random : Pseudo-random number generators (PRNG).

Basic functions

val init : int -> unit

Initialize the generator, using the argument as a seed. The same seed will always yield the same sequence of numbers.

val full_init : int array -> unit

Same as Random.init [34] but takes more data as seed.

val self_init : unit -> unit

Initialize the generator with a more-or-less random seed chosen in a system-dependent way.

val bits : unit -> int

Return 30 random bits in a nonnegative integer.

Before 3.12.0 used a different algorithm (affects all the following functions)

val int : int -> int

Random.int bound returns a random integer between 0 (inclusive) and bound (exclusive). bound must be greater than 0 and less than 2^{30}.

val int32 : Int32.t -> Int32.t

Random.int32 bound returns a random integer between 0 (inclusive) and bound (exclusive). bound must be greater than 0.

val nativeint : Nativeint.t -> Nativeint.t

Random.nativeint bound returns a random integer between 0 (inclusive) and bound (exclusive). bound must be greater than 0.

val int64 : Int64.t -> Int64.t

Random.int64 bound returns a random integer between 0 (inclusive) and bound (exclusive). bound must be greater than 0.

val float : float -> float

Random.float bound returns a random oating-point number between 0 (inclusive) and bound (exclusive). If bound is negative, the result is negative or zero. If bound is 0, the result is 0.

val bool : unit -> bool

Random.bool () returns true or false with probability 0.5 each.

Advanced functions

The functions from module State manipulate the current state of the random generator explicitly. This allows using one or several deterministic PRNGs, even in a multi-threaded program, without interference from other parts of the program.

module State :
  sig

    type t

      The type of PRNG states.

    val make : int array -> t

      Create a new state and initialize it with the given seed.

    val make_self_init : unit -> t

      Create a new state and initialize it with a system-dependent low-entropy seed.

    val copy : t -> t

      Return a copy of the given state.

    val bits : t -> int
    val int : t -> int -> int
    val int32 : t -> Int32.t -> Int32.t
    val nativeint : t -> Nativeint.t -> Nativeint.t
    val int64 : t -> Int64.t -> Int64.t
    val float : t -> float -> float
    val bool : t -> bool

      These functions are the same as the basic functions, except that they use (and update) the given PRNG state instead of the default one.

  end

val get_state : unit -> State.t

    Return the current state of the generator used by the basic functions.

val set_state : State.t -> unit

    Set the state of the generator used by the basic functions.

35 Module Scanf : Formatted input functions.

Introduction

Functional input with format strings

The module Scanf provides formatted input functions or scanners

The formatted input functions can read from any kind of input, including strings, les, or anything that can return characters. The more general source of characters is named formatted input channel (or scanning bu er) and has type Scanf.Scanning.in_channel [35]. The more general formatted input function reads from any scanning bu er and is named bscanf.

Generally speaking, the formatted input functions have 3 arguments:

- the rst argument is a source of characters for the input,

- the second argument is a format string that speci es the values to read,

- the third argument is a receiver function that is applied to the values read.

Hence, a typical call to the formatted input function Scanf.bscanf [35] is bscanf ic fmt f , where:

- ic is a source of characters (typically a formatted input channel with type Scanf.Scanning.in_channel [35

- fmt is a format string (the same format strings as those used to print material with module Printf [32] or Format [13]),

- f is a function that has as many arguments as the number of values to read in the input.

A simple example

As suggested above, the expression bscanf ic "%d" f reads a decimal integer n from the source of characters ic and returns f n .

For instance,

- if we use stdin as the source of characters (Scanf.Scanning.stdin [35] is the prede ned formatted input channel that reads from standard input),

- if we de ne the receiver f as let f x = x + 1 ,

then bscanf Scanning.stdin "%d" f reads an integer n from the standard input and returns f n (that is n + 1). Thus, if we evaluate bscanf stdin "%d" f , and then enter 41 at the keyboard, we get 42 as the nal result.

Formatted input as a functional feature

The Caml scanning facility is reminiscent of the corresponding C feature. However, it is also largely di erent, simpler, and yet more powerful: the formatted input functions are higher-order functionals and the parameter passing mechanism is just the regular function application not the variable assignment based mechanism which is typical for formatted input in imperative languages; the Caml format strings also feature useful additions to easily de ne complex tokens; as expected

within a functional programming language, the formatted input functions also support polymorphism, in particular arbitrary interaction with polymorphic user-de ned scanners. Furthermore, the Caml formatted input facility is fully type-checked at compile time.

module Scanning :
  sig

    type in_channel
    type scanbuf = in_channel

        The type of scanning bu ers. A scanning bu er is the source from which a formatted input function gets characters. The scanning bu er holds the current state of the scan, plus a function to get the next char from the input, and a token bu er to store the string matched so far.
        Note: a scanning action may often require to examine one character in advance; when this lookahead character does not belong to the token read, it is stored back in the scanning bu er and becomes the next character yet to be read.

    val stdin : in_channel

        The standard input notion for the Scanf module. Scanning.stdin is the formatted input channel attached to Pervasives.stdin .
        Note: in the interactive system, when input is read from stdin , the newline character that triggers the evaluation is incorporated in the input; thus, the scanning speci cations must properly skip this additional newline character (for instance, simply add a '\n' as the last character of the format string).
        Since: 3.12.0

    val open_in : string -> in_channel

        Scanning.open_in fname returns a formatted input channel for bu erized reading in text mode of le fname.
        Note: open_in returns a formatted input channel that e ciently reads characters in large chunks; in contrast, from_channel below returns formatted input channels that must read one character at a time, leading to a much slower scanning rate.
        Since: 3.12.0

    val open_in_bin : string -> in_channel

        Scanning.open_in_bin fname returns a formatted input channel for bu erized reading in binary mode of le fname.
        Since: 3.12.0

    val close_in : in_channel -> unit

        Closes the Pervasives.input_channel associated with the given Scanning.in_channel formatted input channel.
        Since: 3.12.0

val from_file : string -> in_channel

An alias for open_in above.

val from_file_bin : string -> in_channel

An alias for open_in_bin above.

val from_string : string -> in_channel

Scanning.from_string s   returns a formatted input channel which reads from the given string. Reading starts from the rst character in the string. The end-of-input condition is set when the end of the string is reached.

val from_function : (unit -> char) -> in_channel

Scanning.from_function f   returns a formatted input channel with the given function as its reading method.
When scanning needs one more character, the given function is called.
When the function has no more character to provide, it must signal an end-of-input condition by raising the exception End_of_file .

val from_channel : Pervasives.in_channel -> in_channel

Scanning.from_channel ic   returns a formatted input channel which reads from the regular input channel ic argument, starting at the current reading position.

val end_of_input : in_channel -> bool

Scanning.end_of_input ic   tests the end-of-input condition of the given formatted input channel.

val beginning_of_input : in_channel -> bool

Scanning.beginning_of_input ic   tests the beginning of input condition of the given formatted input channel.

val name_of_input : in_channel -> string

Scanning.name_of_input ic   returns the name of the character source for the formatted input channel ic .
Since: 3.09.0

val stdib : in_channel

A deprecated alias for Scanning.stdin , the scanning bu er reading from Pervasives.stdin   .

end

Formatted input channel

Type of formatted input functions

type ('a, 'b, 'c, 'd) scanner = ('a, Scanning.in_channel, 'b, 'c, 'a -> 'd, 'd) format6 -> 'c

The type of formatted input scanners: ('a, 'b, 'c, 'd) scanner is the type of a formatted input function that reads from some formatted input channel according to some format string; more precisely, if scan is some formatted input function, then scan ic fmt f applies f to the arguments specified by the format string fmt, when scan has read those arguments from the formatted input channel ic.

For instance, the scanf function below has type ('a, 'b, 'c, 'd) scanner, since it is a formatted input function that reads from Scanning.stdin : scanf fmt f applies f to the arguments specified by fmt, reading those arguments from Pervasives.stdin as expected.

If the format fmt has some %r indications, the corresponding input functions must be provided before the receiver f argument. For instance, if read_elem is an input function for values of type t, then bscanf ic "%r;" read_elem f reads a value v of type t followed by a ';' character, and returns f v.

Since: 3.10.0

exception Scan_failure of string

The exception that formatted input functions raise when the input cannot be read according to the given format.

The general formatted input function

val bscanf : Scanning.in_channel -> ('a, 'b, 'c, 'd) scanner

bscanf ic fmt r1 ... rN f reads arguments for the function f, from the formatted input channel ic, according to the format string fmt, and applies f to these values. The result of this call to f is returned as the result of the entire bscanf call. For instance, if f is the function fun s i -> i + 1, then Scanf.sscanf "x= 1" "%s = %i" f returns 2.

Arguments r1 to rN are user-defined input functions that read the argument corresponding to a %r conversion.

Format string description

The format is a character string which contains three types of objects:

- plain characters, which are simply matched with the characters of the input (with a special case for space and line feed, see [35]),

- conversion specifications, each of which causes reading and conversion of one argument for the function f (see [35]),

- scanning indications to specify boundaries of tokens (see scanning [35]).

The space character in format strings

As mentioned above, a plain character in the format string is just matched with the next character of the input; however, two characters are special exceptions to this rule: the space character (' ' or ASCII code 32) and the line feed character '\n' or ASCII code 10). A space does not match a single space character, but any amount of whitespace in the input. More precisely, a space

101

inside the format string matches any number of tab, space, line feed and carriage return characters. Similarly, a line feed character in the format string matches either a single line feed or a carriage return followed by a line feed.

Matching any amount of whitespace, a space in the format string also matches no amount of whitespace at all; hence, the call bscanf ib "Price = %d $" (fun p -> p)   succeeds and returns 1 when reading an input with various whitespace in it, such as Price = 1 $, Price = 1 $, or even Price=1$.

Conversion speci cations in format strings

Conversion speci cations consist in the %character, followed by an optional ag, an optional eld width, and followed by one or two conversion characters. The conversion characters and their meanings are:

- d: reads an optionally signed decimal integer.

- i : reads an optionally signed integer (usual input conventions for decimal 0-9+), hexadecimal (0x[0-9a-f]+   and 0X[0-9A-F]+), octal (0o[0-7]+), and binary (0b[0-1]+) notations are understood).

- u: reads an unsigned decimal integer.

- x or X: reads an unsigned hexadecimal integer [0-9a-f]+   or [0-9A-F]+).

- o: reads an unsigned octal integer [0-7]+).

- s: reads a string argument that spreads as much as possible, until the following bounding condition holds:

    a whitespace has been found (see [35]),

    a scanning indication (see scanning [35]) has been encountered,

    the end-of-input has been reached.

  Hence, this conversion always succeeds: it returns an empty string, if the bounding condition holds when the scan begins.

- S: reads a delimited string argument (delimiters and special escaped characters follow the lexical conventions of Caml).

- c: reads a single character. To test the current input character without reading it, specify a null eld width, i.e. use speci cation %0c Raise Invalid_argument , if the eld width speci cation is greater than 1.

- C: reads a single delimited character (delimiters and special escaped characters follow the lexical conventions of Caml).

- f , e, E, g, G reads an optionally signed oating-point number in decimal notation, in the style dddd.ddd e/E+-dd.

- F: reads a oating point number according to the lexical conventions of Caml (hence the decimal point is mandatory if the exponent part is not mentioned).

- B: reads a boolean argument (true or false).

- b: reads a boolean argument (for backward compatibility; do not use in new programs).

- ld, li, lu, lx, lX, lo: reads an int32 argument to the format specified by the second letter for regular integers.

- nd, ni, nu, nx, nX, no: reads a nativeint argument to the format specified by the second letter for regular integers.

- Ld, Li, Lu, Lx, LX, Lo: reads an int64 argument to the format specified by the second letter for regular integers.

- [range]: reads characters that matches one of the characters mentioned in the range of characters range (or not mentioned in it, if the range starts with ^). Reads a string that can be empty, if the next input character does not match the range. The set of characters from c1 to c2 (inclusively) is denoted by c1-c2. Hence, %[0-9] returns a string representing a decimal number or an empty string if no decimal digit is found; similarly, %[\\048-\\057\\065-\\070] returns a string of hexadecimal digits. If a closing bracket appears in a range, it must occur as the first character of the range (or just after the ^ in case of range negation); hence []] matches a] character and [^]] matches any character that is not].

- r: user-defined reader. Takes the next ri formatted input function and applies it to the scanning buffer ib to read the next argument. The input function ri must therefore have type Scanning.in_channel -> 'a and the argument read has type 'a.

- { fmt %}: reads a format string argument. The format string read must have the same type as the format string specification fmt. For instance, "%{ %i %}" reads any format string that can read a value of type int; hence, if s is the string "fmt:\"number is %u\"", then Scanf.sscanf s "fmt: %{%i%}" succeeds and returns the format string "number is %u".

- \(fmt %\): scanning format substitution. Reads a format string and then goes on scanning with the format string read, instead of using fmt. The format string read must have the same type as the format string specification fmt that it replaces. For instance, "%(%i %)" reads any format string that can read a value of type int. Returns the format string read, and the value read using the format string read. Hence, if s is the string "\"%4d\"1234.00", then Scanf.sscanf s "%(%i%)" (fun fmt i -> fmt, i) evaluates to ("%4d", 1234). If the special flag _ is used, the conversion discards the format string read and only returns the value read with the format string read. Hence, if s is the string "\"%4d\"1234.00", then Scanf.sscanf s "%_(%i%)" is simply equivalent to Scanf.sscanf "1234.00" "%4d".

- l: returns the number of lines read so far.

- n: returns the number of characters read so far.

- N or L: returns the number of tokens read so far.

- !: matches the end of input condition.

- %: matches one % character in the input.

103

- , : the no-op delimiter for conversion speci cations.

Following the %character that introduces a conversion, there may be the special ag _: the conversion that follows occurs as usual, but the resulting value is discarded. For instance, if f is the function fun i -> i + 1 , and s is the string "x = 1" , then Scanf.sscanf s "%_s = %i" f returns 2.

The eld width is composed of an optional integer literal indicating the maximal width of the token to read. For instance, %6dreads an integer, having at most 6 decimal digits; %4f reads a oat with at most 4 characters; and %8[\\000-\\255]   returns the next 8 characters (or all the characters still available, if fewer than 8 characters are available in the input).

Notes:

- as mentioned above, a%sconversion always succeeds, even if there is nothing to read in the input: in this case, it simply returns "" .

- in addition to the relevant digits, '_' characters may appear inside numbers (this is reminiscent to the usual Caml lexical conventions). If stricter scanning is desired, use the range conversion facility instead of the number conversions.

- the scanf facility is not intended for heavy duty lexical analysis and parsing. If it appears not expressive enough for your needs, several alternative exists: regular expressions (module Str), stream parsers, ocamllex -generated lexers, ocamlyacc-generated parsers.

Scanning indications in format strings

Scanning indications appear just after the string conversions %sand %[range] to delimit the end of the token. A scanning indication is introduced by a @character, followed by some constant character c. It means that the string token should end just before the next matching c (which is skipped). If no c character is encountered, the string token spreads as much as possible. For instance, "%s@\t" reads a string up to the next tab character or to the end of input. If a scanning indication @cdoes not follow a string conversion, it is treated as a plain c character.

Note:

- the scanning indications introduce slight di erences in the syntax of Scanf format strings, compared to those used for the Printf   module. However, the scanning indications are similar to those used in the Format module; hence, when producing formatted text to be scanned by !Scanf.bscanf , it is wise to use printing functions from the Format module (or, if you need to use functions from Printf   , banish or carefully double check the format strings that contain '@' characters).

Exceptions during scanning

Scanners may raise the following exceptions when the input cannot be read according to the format string:

- Raise Scanf.Scan_failure   if the input does not match the format.

- Raise Failure   if a conversion to a number is not possible.

- Raise `End_of_file` if the end of input is encountered while some more characters are needed to read the current conversion speci cation.

- Raise `Invalid_argument` if the format string is invalid.

Note:

- as a consequence, scanning `%s` conversion never raises exception `End_of_file` : if the end of input is reached the conversion succeeds and simply returns the characters read so far, "br if none were ever read.

Specialised formatted input functions

val fscanf : Pervasives.in_channel -> ('a, 'b, 'c, 'd) scanner

Same as `Scanf.bscanf` [35], but reads from the given regular input channel.

Warning: since all formatted input functions operate from a formatted input channel, be aware that each `fscanf` invocation will operate with a formatted input channel reading from the given channel. This extra level of bu erization can lead to a strange scanning behaviour if you use low level primitives on the channel (reading characters, seeking the reading position, and so on).

As a consequence, never mix direct low level reading and high level scanning from the same regular input channel.

val sscanf : string -> ('a, 'b, 'c, 'd) scanner

Same as `Scanf.bscanf` [35], but reads from the given string.

val scanf : ('a, 'b, 'c, 'd) scanner

Same as `Scanf.bscanf` [35], but reads from the prede ned formatted input channel `Scanf.Scanning.stdin` [35] that is connected to `Pervasives.stdin` .

val kscanf :
  Scanning.in_channel ->
  (Scanning.in_channel -> exn -> 'a) -> ('b, 'c, 'd, 'a) scanner

Same as `Scanf.bscanf` [35], but takes an additional function argument `ef` that is called in case of error: if the scanning process or some conversion fails, the scanning function aborts and calls the error handling function `ef` with the formatted input channel and the exception that aborted the scanning process as arguments.

Reading format strings from input

val bscanf_format :
  Scanning.in_channel ->
  ('a, 'b, 'c, 'd, 'e, 'f) format6 ->
  (('a, 'b, 'c, 'd, 'e, 'f) format6 -> 'g) -> 'g

`bscanf_format ic fmt f` reads a format string token from the formatted input channel `ic` , according to the given format string `fmt`, and applies `f` to the resulting format string value. Raise `Scan_failure` if the format string value read does not have the same type as `fmt` .

Since: 3.09.0

val sscanf_format :
  string ->
  ('a, 'b, 'c, 'd, 'e, 'f) format6 ->
  (('a, 'b, 'c, 'd, 'e, 'f) format6 -> 'g) -> 'g

    Same as Scanf.bscanf_format [35], but reads from the given string.

    Since: 3.09.0

val format_from_string :
  string ->
  ('a, 'b, 'c, 'd, 'e, 'f) format6 -> ('a, 'b, 'c, 'd, 'e, 'f) format6

    format_from_string s fmt converts a string argument to a format string, according to the given format string fmt. Raise Scan_failure if s, considered as a format string, does not have the same type as fmt.

    Since: 3.10.0

36   Module Set : Sets over ordered types.

This module implements the set data structure, given a total ordering function over the set elements. All operations over sets are purely applicative (no side-e ects). The implementation uses balanced binary trees, and is therefore reasonably e cient: insertion and membership take time logarithmic in the size of the set, for instance.

module type OrderedType =
  sig

    type t

        The type of the set elements.

    val compare : t -> t -> int

        A total ordering function over the set elements. This is a two-argument function f such that f e1 e2 is zero if the elements e1 and e2 are equal, f e1 e2 is strictly negative if e1 is smaller than e2, and f e1 e2 is strictly positive if e1 is greater than e2. Example: a suitable ordering function is the generic structural comparison function Pervasives.compare [30].

  end

    Input signature of the functor Set.Make [36].

module type S =
  sig

    type elt

        The type of the set elements.

106

```
type t
```

The type of sets.

```
val empty : t
```

The empty set.

```
val is_empty : t -> bool
```

Test whether a set is empty or not.

```
val mem : elt -> t -> bool
```

mem x s tests whether x belongs to the sets.

```
val add : elt -> t -> t
```

add x s returns a set containing all elements of s, plus x. If x was already in s, s is returned unchanged.

```
val singleton : elt -> t
```

singleton x returns the one-element set containing only x.

```
val remove : elt -> t -> t
```

remove x s returns a set containing all elements of s, except x. If x was not in s, s is returned unchanged.

```
val union : t -> t -> t
```

Set union.

```
val inter : t -> t -> t
```

Set intersection.

```
val diff : t -> t -> t
```

Set difference.

```
val compare : t -> t -> int
```

Total ordering between sets. Can be used as the ordering function for doing sets of sets.

```
val equal : t -> t -> bool
```

equal s1 s2 tests whether the sets s1 and s2 are equal, that is, contain equal elements.

```
val subset : t -> t -> bool
```

subset s1 s2 tests whether the set s1 is a subset of the set s2.

val iter : (elt -> unit) -> t -> unit

> iter f s   applies f in turn to all elements of s. The elements of s are presented to f in increasing order with respect to the ordering over the type of the elements.

val fold : (elt -> 'a -> 'a) -> t -> 'a -> 'a

> fold f s a   computes (f xN ... (f x2 (f x1 a))...)   , where x1 ... xN are the elements of s, in increasing order.

val for_all : (elt -> bool) -> t -> bool

> for_all p s   checks if all elements of the set satisfy the predicate p.

val exists : (elt -> bool) -> t -> bool

> exists p s   checks if at least one element of the set satis es the predicate p.

val filter : (elt -> bool) -> t -> t

> filter p s   returns the set of all elements in s that satisfy predicate p.

val partition : (elt -> bool) -> t -> t * t

> partition p s   returns a pair of sets (s1, s2) , where s1 is the set of all the elements of s that satisfy the predicate p, and s2 is the set of all the elements of s that do not satisfy p.

val cardinal : t -> int

> Return the number of elements of a set.

val elements : t -> elt list

> Return the list of all elements of the given set. The returned list is sorted in increasing order with respect to the ordering Ord.compare, where Ord is the argument given to Set.Make [36].

val min_elt : t -> elt

> Return the smallest element of the given set (with respect to the Ord.compare ordering), or raise Not_found if the set is empty.

val max_elt : t -> elt

> Same as Set.S.min_elt [36], but returns the largest element of the given set.

val choose : t -> elt

> Return one element of the given set, or raise Not_found if the set is empty. Which element is chosen is unspeci ed, but equal elements will be chosen for equal sets.

val split : elt -> t -> t * bool * t

> split x s returns a triple (l, present, r), where l is the set of elements of s that are strictly less than x; r is the set of elements of s that are strictly greater than x; present is false if s contains no element equal to x, or true if s contains an element equal to x.

end

> Output signature of the functor Set.Make [36].

module Make :
  functor (Ord : OrderedType) -> S with type elt = Ord.t
> Functor building an implementation of the set structure given a totally ordered type.

37 Module Sort : Sorting and merging lists.

This module is obsolete and exists only for backward compatibility. The sorting functions in Array [2] and List [21] should be used instead. The new functions are faster and use less memory. Sorting and merging lists.

val list : ('a -> 'a -> bool) -> 'a list -> 'a list

> Sort a list in increasing order according to an ordering predicate. The predicate should return true if its rst argument is less than or equal to its second argument.

val array : ('a -> 'a -> bool) -> 'a array -> unit

> Sort an array in increasing order according to an ordering predicate. The predicate should return true if its rst argument is less than or equal to its second argument. The array is sorted in place.

val merge : ('a -> 'a -> bool) -> 'a list -> 'a list -> 'a list

> Merge two lists according to the given predicate. Assuming the two argument lists are sorted according to the predicate, merge returns a sorted list containing the elements from the two lists. The behavior is unde ned if the two argument lists were not sorted.

38 Module Stack : Last-in rst-out stacks.

This module implements stacks (LIFOs), with in-place modi cation.

type 'a t

> The type of stacks containing elements of type 'a.

exception Empty

109

Raised when Stack.pop [38] or Stack.top [38] is applied to an empty stack.

val create : unit -> 'a t
  Return a new stack, initially empty.

val push : 'a -> 'a t -> unit
  push x s adds the element x at the top of stack s.

val pop : 'a t -> 'a
  pop s removes and returns the topmost element in stack s, or raises Empty if the stack is empty.

val top : 'a t -> 'a
  top s returns the topmost element in stack s, or raises Empty if the stack is empty.

val clear : 'a t -> unit
  Discard all elements from a stack.

val copy : 'a t -> 'a t
  Return a copy of the given stack.

val is_empty : 'a t -> bool
  Return true if the given stack is empty, false otherwise.

val length : 'a t -> int
  Return the number of elements in a stack.

val iter : ('a -> unit) -> 'a t -> unit
  iter f s applies f in turn to all elements of s, from the element at the top of the stack to the element at the bottom of the stack. The stack itself is unchanged.

39 Module StdLabels : Standard labeled libraries.

This meta-module provides labelized version of the Array [2], List [21] and String [41] modules.
  They only differ by their labels. Detailed interfaces can be found in arrayLabels.mli , listLabels.mli and stringLabels.mli .

module Array :
  sig
    val length : 'a array -> int
    val get : 'a array -> int -> 'a
    val set : 'a array -> int -> 'a -> unit
    val make : int -> 'a -> 'a array

```
    val create : int -> 'a -> 'a array
    val init : int -> f:(int -> 'a) -> 'a array
    val make_matrix : dimx:int -> dimy:int -> 'a -> 'a array array
    val create_matrix : dimx:int -> dimy:int -> 'a -> 'a array array
    val append : 'a array -> 'a array -> 'a array
    val concat : 'a array list -> 'a array
    val sub : 'a array -> pos:int -> len:int -> 'a array
    val copy : 'a array -> 'a array
    val fill : 'a array -> pos:int -> len:int -> 'a -> unit
    val blit :
       src:'a array -> src_pos:int -> dst:'a array -> dst_pos:int -> len:int -> unit
    val to_list : 'a array -> 'a list
    val of_list : 'a list -> 'a array
    val iter : f:('a -> unit) -> 'a array -> unit
    val map : f:('a -> 'b) -> 'a array -> 'b array
    val iteri : f:(int -> 'a -> unit) -> 'a array -> unit
    val mapi : f:(int -> 'a -> 'b) -> 'a array -> 'b array
    val fold_left : f:('a -> 'b -> 'a) -> init:'a -> 'b array -> 'a
    val fold_right : f:('a -> 'b -> 'b) -> 'a array -> init:'b -> 'b
    val sort : cmp:('a -> 'a -> int) -> 'a array -> unit
    val stable_sort : cmp:('a -> 'a -> int) -> 'a array -> unit
    val fast_sort : cmp:('a -> 'a -> int) -> 'a array -> unit
    val unsafe_get : 'a array -> int -> 'a
    val unsafe_set : 'a array -> int -> 'a -> unit
  end

module List :
  sig

    val length : 'a list -> int
    val hd : 'a list -> 'a
    val tl : 'a list -> 'a list
    val nth : 'a list -> int -> 'a
    val rev : 'a list -> 'a list
    val append : 'a list -> 'a list -> 'a list
    val rev_append : 'a list -> 'a list -> 'a list
    val concat : 'a list list -> 'a list
    val flatten : 'a list list -> 'a list
    val iter : f:('a -> unit) -> 'a list -> unit
```

```
    val map : f:('a -> 'b) -> 'a list -> 'b list
    val rev_map : f:('a -> 'b) -> 'a list -> 'b list
    val fold_left : f:('a -> 'b -> 'a) -> init:'a -> 'b list -> 'a
    val fold_right : f:('a -> 'b -> 'b) -> 'a list -> init:'b -> 'b
    val iter2 : f:('a -> 'b -> unit) -> 'a list -> 'b list -> unit
    val map2 : f:('a -> 'b -> 'c) -> 'a list -> 'b list -> 'c list
    val rev_map2 : f:('a -> 'b -> 'c) -> 'a list -> 'b list -> 'c list
    val fold_left2 :
      f:('a -> 'b -> 'c -> 'a) -> init:'a -> 'b list -> 'c list -> 'a
    val fold_right2 :
      f:('a -> 'b -> 'c -> 'c) -> 'a list -> 'b list -> init:'c -> 'c
    val for_all : f:('a -> bool) -> 'a list -> bool
    val exists : f:('a -> bool) -> 'a list -> bool
    val for_all2 : f:('a -> 'b -> bool) -> 'a list -> 'b list -> bool
    val exists2 : f:('a -> 'b -> bool) -> 'a list -> 'b list -> bool
    val mem : 'a -> set:'a list -> bool
    val memq : 'a -> set:'a list -> bool
    val find : f:('a -> bool) -> 'a list -> 'a
    val filter : f:('a -> bool) -> 'a list -> 'a list
    val find_all : f:('a -> bool) -> 'a list -> 'a list
    val partition : f:('a -> bool) -> 'a list -> 'a list * 'a list
    val assoc : 'a -> ('a * 'b) list -> 'b
    val assq : 'a -> ('a * 'b) list -> 'b
    val mem_assoc : 'a -> map:('a * 'b) list -> bool
    val mem_assq : 'a -> map:('a * 'b) list -> bool
    val remove_assoc : 'a -> ('a * 'b) list -> ('a * 'b) list
    val remove_assq : 'a -> ('a * 'b) list -> ('a * 'b) list
    val split : ('a * 'b) list -> 'a list * 'b list
    val combine : 'a list -> 'b list -> ('a * 'b) list
    val sort : cmp:('a -> 'a -> int) -> 'a list -> 'a list
    val stable_sort : cmp:('a -> 'a -> int) -> 'a list -> 'a list
    val fast_sort : cmp:('a -> 'a -> int) -> 'a list -> 'a list
    val merge : cmp:('a -> 'a -> int) -> 'a list -> 'a list -> 'a list
  end

module String :
  sig
    val length : string -> int
    val get : string -> int -> char
```

```
      val set : string -> int -> char -> unit
      val create : int -> string
      val make : int -> char -> string

      val fill : string -> pos:int -> len:int -> char -> unit
      val blit :
        src:string -> src_pos:int -> dst:string -> dst_pos:int -> len:int -> unit
      val concat : sep:string -> string list -> string
      val iter : f:(char -> unit) -> string -> unit
      val escaped : string -> string
      val index : string -> char -> int
      val rindex : string -> char -> int
      val index_from : string -> int -> char -> int
      val rindex_from : string -> int -> char -> int
      val contains : string -> char -> bool
      val contains_from : string -> int -> char -> bool
      val rcontains_from : string -> int -> char -> bool
      val uppercase : string -> string
      val lowercase : string -> string
      val capitalize : string -> string
      val uncapitalize : string -> string
      type t = string
      val compare : t -> t -> int
      val unsafe_get : string -> int -> char
      val unsafe_set : string -> int -> char -> unit
      val unsafe_blit :
        src:string -> src_pos:int -> dst:string -> dst_pos:int -> len:int -> unit
      val unsafe_fill : string -> pos:int -> len:int -> char -> unit
   end
```

40   Module Stream : Streams and parsers.

type 'a t
    The type of streams holding values of type 'a .

exception Failure
    Raised by parsers when none of the rst components of the stream patterns is accepted.

113

exception Error of string

    Raised by parsers when the rst component of a stream pattern is accepted, but one of the following components is rejected.

   Stream builders

  Warning: these functions create streams with fast access; it is illegal to mix them with streams built with [< >] ; would raise Failure when accessing such mixed streams.

val from : (int -> 'a option) -> 'a t

    Stream.from f returns a stream built from the function f . To create a new stream element, the function f is called with the current stream count. The user function f must return either Some <value> for a value or None to specify the end of the stream.

val of_list : 'a list -> 'a t

    Return the stream holding the elements of the list in the same order.

val of_string : string -> char t

    Return the stream of the characters of the string parameter.

val of_channel : Pervasives.in_channel -> char t

    Return the stream of the characters read from the input channel.

   Stream iterator

val iter : ('a -> unit) -> 'a t -> unit

    Stream.iter f s scans the whole stream s, applying function f in turn to each stream element encountered.

   Prede ned parsers

val next : 'a t -> 'a

    Return the rst element of the stream and remove it from the stream. Raise Stream.Failure if the stream is empty.

val empty : 'a t -> unit

    Return () if the stream is empty, else raise Stream.Failure .

   Useful functions

val peek : 'a t -> 'a option

    Return Some of "the rst element" of the stream, or None if the stream is empty.

val junk : 'a t -> unit

    Remove the rst element of the stream, possibly unfreezing it before.

val count : 'a t -> int

    Return the current count of the stream elements, i.e. the number of the stream elements discarded.

val npeek : int -> 'a t -> 'a list

    npeek n returns the list of the n rst elements of the stream, or all its remaining elements if less than n elements are available.

41 Module String : String operations.

Given a string s of length l , we call character number in s the index of a character in s. Indexes start at 0, and we will call a character number valid in s if it falls within the range [0...l-1] . A position is the point between two characters or at the beginning or end of the string. We call a position valid in s if it falls within the range [0...l] . Note that character number n is between positions n and n+1.

Two parameters start and len are said to designate a valid substring of s if len >= 0 and start and start+len are valid positions in s.

val length : string -> int

    Return the length (number of characters) of the given string.

val get : string -> int -> char

    String.get s n returns character number n in string s. You can also write s.[n] instead of String.get s n .

    Raise Invalid_argument if n not a valid character number in s.

val set : string -> int -> char -> unit

    String.set s n c modi es string s in place, replacing the character number n by c. You can also write s.[n] <- c instead of String.set s n c .

    Raise Invalid_argument if n is not a valid character number in s.

val create : int -> string

    String.create n returns a fresh string of length n. The string initially contains arbitrary characters.

    Raise Invalid_argument if n < 0 or n > Sys.max_string_length [43].

val make : int -> char -> string

    String.make n c returns a fresh string of length n, lled with the character c.

    Raise Invalid_argument if n < 0 or n > Sys.max_string_length [43].

val copy : string -> string

    Return a copy of the given string.

val sub : string -> int -> int -> string

    String.sub s start len returns a fresh string of length len , containing the substring of s that starts at position start and has length len .

    Raise Invalid_argument if start and len do not designate a valid substring of s.

val fill : string -> int -> int -> char -> unit

    String.fill s start len c modi es string s in place, replacing len characters by c, starting at start .

    Raise Invalid_argument if start and len do not designate a valid substring of s.

val blit : string -> int -> string -> int -> int -> unit

> String.blit src srcoff dst dstoff len copies len characters from string src , starting at character number srcoff , to string dst , starting at character number dstoff . It works correctly even if src and dst are the same string, and the source and destination intervals overlap.
>
> Raise Invalid_argument if srcoff and len do not designate a valid substring of src , or if dstoff and len do not designate a valid substring of dst .

val concat : string -> string list -> string

> String.concat sep sl concatenates the list of strings sl , inserting the separator string sep between each.

val iter : (char -> unit) -> string -> unit

> String.iter f s applies function f in turn to all the characters of s. It is equivalent to f s.[0]; f s.[1]; ...; f s.[String.length s - 1]; () .

val escaped : string -> string

> Return a copy of the argument, with special characters represented by escape sequences, following the lexical conventions of Objective Caml. If there is no special character in the argument, return the original string itself, not a copy.

val index : string -> char -> int

> String.index s c returns the character number of the rst occurrence of character c in string s.
>
> Raise Not_found if c does not occur in s.

val rindex : string -> char -> int

> String.rindex s c returns the character number of the last occurrence of character c in string s.
>
> Raise Not_found if c does not occur in s.

val index_from : string -> int -> char -> int

> String.index_from s i c returns the character number of the rst occurrence of character c in string s after position i . String.index s c is equivalent to String.index_from s 0 c .
>
> Raise Invalid_argument if i is not a valid position in s. Raise Not_found if c does not occur in s after position i .

val rindex_from : string -> int -> char -> int

> String.rindex_from s i c returns the character number of the last occurrence of character c in string s before position i+1 . String.rindex s c is equivalent to String.rindex_from s (String.length s - 1) c .
>
> Raise Invalid_argument if i+1 is not a valid position in s. Raise Not_found if c does not occur in s before position i+1 .

val contains : string -> char -> bool

    String.contains s c tests if character c appears in the string s.

val contains_from : string -> int -> char -> bool

    String.contains_from s start c tests if character c appears in s after position start .
    String.contains s c is equivalent to String.contains_from s 0 c .

    Raise Invalid_argument if start is not a valid position in s.

val rcontains_from : string -> int -> char -> bool

    String.rcontains_from s stop c tests if character c appears in s before position stop+1.

    Raise Invalid_argument if stop < 0 or stop+1 is not a valid position in s.

val uppercase : string -> string

    Return a copy of the argument, with all lowercase letters translated to uppercase, including accented letters of the ISO Latin-1 (8859-1) character set.

val lowercase : string -> string

    Return a copy of the argument, with all uppercase letters translated to lowercase, including accented letters of the ISO Latin-1 (8859-1) character set.

val capitalize : string -> string

    Return a copy of the argument, with the rst character set to uppercase.

val uncapitalize : string -> string

    Return a copy of the argument, with the rst character set to lowercase.

type t = string

    An alias for the type of strings.

val compare : t -> t -> int

    The comparison function for strings, with the same speci cation as Pervasives.compare [30]. Along with the type t , this function compare allows the module String to be passed as argument to the functors Set.Make [36] and Map.Make [23].

42 Module StringLabels : String operations.

val length : string -> int

    Return the length (number of characters) of the given string.

val get : string -> int -> char

String.get s n returns character number n in string s. The first character is character number 0. The last character is character number String.length s - 1. You can also write s.[n] instead of String.get s n.

Raise Invalid_argument "index out of bounds" if n is outside the range 0 to (String.length s - 1).

val set : string -> int -> char -> unit

String.set s n c modifies string s in place, replacing the character number n by c. You can also write s.[n] <- c instead of String.set s n c. Raise Invalid_argument "index out of bounds" if n is outside the range 0 to (String.length s - 1).

val create : int -> string

String.create n returns a fresh string of length n. The string initially contains arbitrary characters. Raise Invalid_argument if n < 0 or n > Sys.max_string_length.

val make : int -> char -> string

String.make n c returns a fresh string of length n, filled with the character c. Raise Invalid_argument if n < 0 or n > Sys.max_string_length [43].

val copy : string -> string

Return a copy of the given string.

val sub : string -> pos:int -> len:int -> string

String.sub s start len returns a fresh string of length len, containing the characters number start to start + len - 1 of string s. Raise Invalid_argument if start and len do not designate a valid substring of s; that is, if start < 0, or len < 0, or start + len > StringLabels.length [42] s.

val fill : string -> pos:int -> len:int -> char -> unit

String.fill s start len c modifies string s in place, replacing the characters number start to start + len - 1 by c. Raise Invalid_argument if start and len do not designate a valid substring of s.

val blit :
  src:string -> src_pos:int -> dst:string -> dst_pos:int -> len:int -> unit

String.blit src srcoff dst dstoff len copies len characters from string src, starting at character number srcoff, to string dst, starting at character number dstoff. It works correctly even if src and dst are the same string, and the source and destination chunks overlap. Raise Invalid_argument if srcoff and len do not designate a valid substring of src, or if dstoff and len do not designate a valid substring of dst.

val concat : sep:string -> string list -> string

String.concat sep sl concatenates the list of strings sl, inserting the separator string sep between each.

val iter : f:(char -> unit) -> string -> unit

> String.iter f s   applies function f in turn to all the characters of s. It is equivalent to f s.[0]; f s.[1]; ...; f s.[String.length s - 1]; ()   .

val escaped : string -> string

> Return a copy of the argument, with special characters represented by escape sequences, following the lexical conventions of Objective Caml. If there is no special character in the argument, return the original string itself, not a copy.

val index : string -> char -> int

> String.index s c   returns the position of the leftmost occurrence of character c in string s. Raise Not_found if c does not occur in s.

val rindex : string -> char -> int

> String.rindex s c   returns the position of the rightmost occurrence of character c in string s. Raise Not_found if c does not occur in s.

val index_from : string -> int -> char -> int

> Same as StringLabels.index   [42], but start searching at the character position given as second argument. String.index s c   is equivalent to String.index_from s 0 c .

val rindex_from : string -> int -> char -> int

> Same as StringLabels.rindex   [42], but start searching at the character position given as second argument. String.rindex s c   is equivalent to String.rindex_from s (String.length s - 1) c   .

val contains : string -> char -> bool

> String.contains s c   tests if character c appears in the string s.

val contains_from : string -> int -> char -> bool

> String.contains_from s start c   tests if character c appears in the substring of s starting from start   to the end of s. Raise Invalid_argument   if start   is not a valid index of s.

val rcontains_from : string -> int -> char -> bool

> String.rcontains_from s stop c   tests if character c appears in the substring of s starting from the beginning of s to index stop . Raise Invalid_argument   if stop is not a valid index of s.

val uppercase : string -> string

> Return a copy of the argument, with all lowercase letters translated to uppercase, including accented letters of the ISO Latin-1 (8859-1) character set.

val lowercase : string -> string

> Return a copy of the argument, with all uppercase letters translated to lowercase, including accented letters of the ISO Latin-1 (8859-1) character set.

val capitalize : string -> string

    Return a copy of the argument, with the rst character set to uppercase.

val uncapitalize : string -> string

    Return a copy of the argument, with the rst character set to lowercase.

type t = string

    An alias for the type of strings.

val compare : t -> t -> int

    The comparison function for strings, with the same speci cation as
    Pervasives.compare [30]. Along with the type t , this function compare allows the module
    String to be passed as argument to the functors Set.Make [36] and Map.Make [23].

43 Module Sys : System interface.

val argv : string array

    The command line arguments given to the process. The rst element is the command name
    used to invoke the program. The following elements are the command-line arguments given
    to the program.

val executable_name : string

    The name of the le containing the executable currently running.

val file_exists : string -> bool

    Test if a le with the given name exists.

val is_directory : string -> bool

    Returns true if the given name refers to a directory, false if it refers to another kind of le.
    Raise Sys_error if no le exists with the given name.

    Since: 3.10.0

val remove : string -> unit

    Remove the given le name from the le system.

val rename : string -> string -> unit

    Rename a le. The rst argument is the old name and the second is the new name. If there
    is already another le under the new name, rename may replace it, or raise an exception,
    depending on your operating system.

val getenv : string -> string

Return the value associated to a variable in the process environment. Raise `Not_found` if the variable is unbound.

val command : string -> int

Execute the given shell command and return its exit code.

val time : unit -> float

Return the processor time, in seconds, used by the program since the beginning of execution.

val chdir : string -> unit

Change the current working directory of the process.

val getcwd : unit -> string

Return the current working directory of the process.

val readdir : string -> string array

Return the names of all les present in the given directory. Names denoting the current directory and the parent directory ("." and ".." in Unix) are not returned. Each string in the result is a le name rather than a complete path. There is no guarantee that the name strings in the resulting array will appear in any speci c order; they are not, in particular, guaranteed to appear in alphabetical order.

val interactive : bool Pervasives.ref

This reference is initially set to `false` in standalone programs and to `true` if the code is being executed under the interactive toplevel system `ocaml`.

val os_type : string

Operating system currently executing the Caml program. One of

- "Unix" (for all Unix versions, including Linux and Mac OS X),
- "Win32" (for MS-Windows, OCaml compiled with MSVC++ or Mingw),
- "Cygwin" (for MS-Windows, OCaml compiled with Cygwin).

val word_size : int

Size of one word on the machine currently executing the Caml program, in bits: 32 or 64.

val max_string_length : int

Maximum length of a string.

val max_array_length : int

Maximum length of a normal array. The maximum length of a oat array is `max_array_length/2` on 32-bit machines and `max_array_length` on 64-bit machines.

Signal handling

```
type signal_behavior =
  | Signal_default
  | Signal_ignore
  | Signal_handle of (int -> unit)
```

What to do when receiving a signal:

- Signal_default : take the default behavior (usually: abort the program)
- Signal_ignore : ignore the signal
- Signal_handle f : call function f , giving it the signal number as argument.

val signal : int -> signal_behavior -> signal_behavior

Set the behavior of the system on receipt of a given signal. The rst argument is the signal number. Return the behavior previously associated with the signal. If the signal number is invalid (or not available on your system), an Invalid_argument exception is raised.

val set_signal : int -> signal_behavior -> unit

Same as Sys.signal [43] but return value is ignored.

Signal numbers for the standard POSIX signals.

val sigabrt : int

Abnormal termination

val sigalrm : int

Timeout

val sigfpe : int

Arithmetic exception

val sighup : int

Hangup on controlling terminal

val sigill : int

Invalid hardware instruction

val sigint : int

Interactive interrupt (ctrl-C)

val sigkill : int

Termination (cannot be ignored)

val sigpipe : int

Broken pipe

val sigquit : int

Interactive termination

val sigsegv : int
Invalid memory reference

val sigterm : int
Termination

val sigusr1 : int
Application-de ned signal 1

val sigusr2 : int
Application-de ned signal 2

val sigchld : int
Child process terminated

val sigcont : int
Continue

val sigstop : int
Stop

val sigtstp : int
Interactive stop

val sigttin : int
Terminal read from background process

val sigttou : int
Terminal write from background process

val sigvtalrm : int
Timeout in virtual time

val sigprof : int
Pro ling interrupt

exception Break
Exception raised on interactive interrupt if Sys.catch_break [43] is on.

val catch_break : bool -> unit
catch_break governs whether interactive interrupt (ctrl-C) terminates the program or raises
the Break exception. Call catch_break true to enable raising Break, and catch_break
false to let the system terminate the program on user interrupt.

123

val ocaml_version : string

> ocaml_version is the version of Objective Caml. It is a string of the form "major.minor[.patchlevel][+additional-info]" , where major, minor, and patchlevel are integers, and additional-info is an arbitrary string. The [.patchlevel] and [+additional-info] parts may be absent.

44 Module Weak : Arrays of weak pointers and hash tables of weak pointers.

Low-level functions

type 'a t

> The type of arrays of weak pointers (weak arrays). A weak pointer is a value that the garbage collector may erase whenever the value is not used any more (through normal pointers) by the program. Note that finalisation functions are run after the weak pointers are erased.

> A weak pointer is said to be full if it points to a value, empty if the value was erased by the GC.

> Notes:

> - Integers are not allocated and cannot be stored in weak arrays.
> - Weak arrays cannot be marshaled using Pervasives.output_value [30] nor the functions of the Marshal[24] module.

val create : int -> 'a t

> Weak.create n returns a new weak array of length n. All the pointers are initially empty. Raise Invalid_argument if n is negative or greater than Sys.max_array_length [43]-1 .

val length : 'a t -> int

> Weak.length ar returns the length (number of elements) of ar .

val set : 'a t -> int -> 'a option -> unit

> Weak.set ar n (Some el) sets the nth cell of ar to be a (full) pointer to el ; Weak.set ar n None sets the nth cell of ar to empty. Raise Invalid_argument "Weak.set" if n is not in the range 0 to Weak.length [44] a - 1 .

val get : 'a t -> int -> 'a option

> Weak.get ar n returns None if the nth cell of ar is empty, Some x (where x is the value) if it is full. Raise Invalid_argument "Weak.get" if n is not in the range 0 to Weak.length [44] a - 1 .

val get_copy : 'a t -> int -> 'a option

Weak.get_copy ar n returns None if the nth cell of ar is empty, Some x (where x is a (shallow) copy of the value) if it is full. In addition to pitfalls with mutable values, the interesting difference with get is that get_copy does not prevent the incremental GC from erasing the value in its current cycle (get may delay the erasure to the next GC cycle). Raise Invalid_argument "Weak.get" if n is not in the range 0 to Weak.length[44] a - 1.

val check : 'a t -> int -> bool

> Weak.check ar n returns true if the nth cell of ar is full, false if it is empty. Note that even if Weak.check ar n returns true, a subsequent Weak.get[44] ar n can return None

val fill : 'a t -> int -> int -> 'a option -> unit

> Weak.fill ar ofs len el sets to el all pointers of ar from ofs to ofs + len - 1. Raise Invalid_argument "Weak.fill" if ofs and len do not designate a valid subarray of a.

val blit : 'a t -> int -> 'a t -> int -> int -> unit

> Weak.blit ar1 off1 ar2 off2 len copies len weak pointers from ar1 (starting at off1) to ar2 (starting at off2). It works correctly even if ar1 and ar2 are the same. Raise Invalid_argument "Weak.blit" if off1 and len do not designate a valid subarray of ar1, or if off2 and len do not designate a valid subarray of ar2.

Weak hash tables

A weak hash table is a hashed set of values. Each value may magically disappear from the set when it is not used by the rest of the program any more. This is normally used to share data structures without inducing memory leaks. Weak hash tables are defined on values from a Hashtbl.HashedType[16] module; the equal relation and hash function are taken from that module. We will say that v is an instance of x if equal x v is true.

The equal relation must be able to work on a shallow copy of the values and give the same result as with the values themselves.

module type S =
  sig

type data

> The type of the elements stored in the table.

type t

> The type of tables that contain elements of type data. Note that weak hash tables cannot be marshaled using Pervasives.output_value [30] or the functions of the Marshal[24] module.

val create : int -> t

> create n creates a new empty weak hash table, of initial size n. The table will grow as needed.

val clear : t -> unit

> Remove all elements from the table.

val merge : t -> data -> data

    merge t x returns an instance of x found in t if any, or else adds x to t and return x.

val add : t -> data -> unit

    add t x adds x to t. If there is already an instance of x in t, it is unspecified which one will be returned by subsequent calls to find and merge

val remove : t -> data -> unit

    remove t x removes from t one instance of x. Does nothing if there is no instance of x in t.

val find : t -> data -> data

    find t x returns an instance of x found in t. Raise Not_found if there is no such element.

val find_all : t -> data -> data list

    find_all t x returns a list of all the instances of x found in t.

val mem : t -> data -> bool

    mem t x returns true if there is at least one instance of x in t, false otherwise.

val iter : (data -> unit) -> t -> unit

    iter f t calls f on each element of t, in some unspecified order. It is not specified what happens if f tries to change t itself.

val fold : (data -> 'a -> 'a) -> t -> 'a -> 'a

    fold f t init computes (f d1 (... (f dN init))) where d1 ... dN are the elements of t in some unspecified order. It is not specified what happens if f tries to change t itself.

val count : t -> int

    Count the number of elements in the table. count t gives the same result as fold (fun _ n -> n+1) t 0 but does not delay the deallocation of the dead elements.

val stats : t -> int * int * int * int * int * int

    Return statistics on the table. The numbers are, in order: table length, number of entries, sum of bucket lengths, smallest bucket length, median bucket length, biggest bucket length.

  end

    The output signature of the functor Weak.Make[44].

module Make :
  functor (H : Hashtbl.HashedType) -> S with type data = H.t
  Functor building an implementation of the weak hash table structure.

45 Module Unix : Interface to the Unix system

Error report

type error =
  | E2BIG

          Argument list too long

  | EACCES

          Permission denied

  | EAGAIN

          Resource temporarily unavailable; try again

  | EBADF

          Bad le descriptor

  | EBUSY

          Resource unavailable

  | ECHILD

          No child process

  | EDEADLK

          Resource deadlock would occur

  | EDOM

          Domain error for math functions, etc.

  | EEXIST

          File exists

  | EFAULT

          Bad address

  | EFBIG

          File too large

  | EINTR

          Function interrupted by signal

  | EINVAL

          Invalid argument

  | EIO

          Hardware I/O error

  | EISDIR

          Is a directory

  | EMFILE

Too many open les by the process

| EMLINK

Too many links

| ENAMETOOLONG

Filename too long

| ENFILE

Too many open les in the system

| ENODEV

No such device

| ENOENT

No such le or directory

| ENOEXEC

Not an executable le

| ENOLCK

No locks available

| ENOMEM

Not enough memory

| ENOSPC

No space left on device

| ENOSYS

Function not supported

| ENOTDIR

Not a directory

| ENOTEMPTY

Directory not empty

| ENOTTY

Inappropriate I/O control operation

| ENXIO

No such device or address

| EPERM

Operation not permitted

| EPIPE

Broken pipe

| ERANGE

Result too large

| EROFS

       Read-only le system

| ESPIPE

       Invalid seek e.g. on a pipe

| ESRCH

       No such process

| EXDEV

       Invalid link

| EWOULDBLOCK

       Operation would block

| EINPROGRESS

       Operation now in progress

| EALREADY

       Operation already in progress

| ENOTSOCK

       Socket operation on non-socket

| EDESTADDRREQ

       Destination address required

| EMSGSIZE

       Message too long

| EPROTOTYPE

       Protocol wrong type for socket

| ENOPROTOOPT

       Protocol not available

| EPROTONOSUPPORT

       Protocol not supported

| ESOCKTNOSUPPORT

       Socket type not supported

| EOPNOTSUPP

       Operation not supported on socket

| EPFNOSUPPORT

       Protocol family not supported

| EAFNOSUPPORT

       Address family not supported by protocol family

| EADDRINUSE

Address already in use

| EADDRNOTAVAIL

Can't assign requested address

| ENETDOWN

Network is down

| ENETUNREACH

Network is unreachable

| ENETRESET

Network dropped connection on reset

| ECONNABORTED

Software caused connection abort

| ECONNRESET

Connection reset by peer

| ENOBUFS

No bu er space available

| EISCONN

Socket is already connected

| ENOTCONN

Socket is not connected

| ESHUTDOWN

Can't send after socket shutdown

| ETOOMANYREFS

Too many references: can't splice

| ETIMEDOUT

Connection timed out

| ECONNREFUSED

Connection refused

| EHOSTDOWN

Host is down

| EHOSTUNREACH

No route to host

| ELOOP

Too many levels of symbolic links

| EOVERFLOW

File size or position not representable

| EUNKNOWNERR of int

>　　Unknown error

The type of error codes. Errors de ned in the POSIX standard and additional errors from UNIX98 and BSD. All other errors are mapped to EUNKNOWNERR.

exception Unix_error of error * string * string

> Raised by the system calls below when an error is encountered. The rst component is the error code; the second component is the function name; the third component is the string parameter to the function, if it has one, or the empty string otherwise.

val error_message : error -> string

> Return a string describing the given error code.

val handle_unix_error : ('a -> 'b) -> 'a -> 'b

> handle_unix_error f x   applies f to x and returns the result. If the exception Unix_error is raised, it prints a message describing the error and exits with code 2.

　Access to the process environment

val environment : unit -> string array

> Return the process environment, as an array of strings with the format variable=value .

val getenv : string -> string

> Return the value associated to a variable in the process environment. Raise Not_found if the variable is unbound. (This function is identical to Sys.getenv .)

val putenv : string -> string -> unit

> Unix.putenv name value sets the value associated to a variable in the process environment. name is the name of the environment variable, and value its new associated value.

　Process handling

type process_status =
  | WEXITED of int

>　　The process terminated normally by exit ; the argument is the return code.

  | WSIGNALED of int

>　　The process was killed by a signal; the argument is the signal number.

  | WSTOPPED of int

>　　The process was stopped by a signal; the argument is the signal number.

The termination status of a process. See module Sys [43] for the de nitions of the standard signal numbers. Note that they are not the numbers used by the OS.

type wait_flag =
  | WNOHANG

>　　do not block if no child has died yet, but immediately return with a pid equal to 0.

| WUNTRACED

报告 report also the children that receive stop signals.

Flags for Unix.waitpid [45].

val execv : string -> string array -> 'a

execv prog args execute the program in le prog, with the arguments args, and the current process environment. These execv* functions never return: on success, the current program is replaced by the new one; on failure, a Unix.Unix_error [45] exception is raised.

val execve : string -> string array -> string array -> 'a

Same as Unix.execv [45], except that the third argument provides the environment to the program executed.

val execvp : string -> string array -> 'a

Same as Unix.execv [45], except that the program is searched in the path.

val execvpe : string -> string array -> string array -> 'a

Same as Unix.execve [45], except that the program is searched in the path.

val fork : unit -> int

Fork a new process. The returned integer is 0 for the child process, the pid of the child process for the parent process.

val wait : unit -> int * process_status

Wait until one of the children processes die, and return its pid and termination status.

val waitpid : wait_flag list -> int -> int * process_status

Same as Unix.wait [45], but waits for the child process whose pid is given. A pid of -1 means wait for any child. A pid of 0 means wait for any child in the same process group as the current process. Negative pid arguments represent process groups. The list of options indicates whether waitpid should return immediately without waiting, or also report stopped children.

val system : string -> process_status

Execute the given command, wait until it terminates, and return its termination status. The string is interpreted by the shell /bin/sh and therefore can contain redirections, quotes, variables, etc. The result WEXITED 127 indicates that the shell couldn't be executed.

val getpid : unit -> int

Return the pid of the process.

val getppid : unit -> int

Return the pid of the parent process.

val nice : int -> int

132

Change the process priority. The integer argument is added to the nice value. (Higher values of the nice value mean lower priorities.) Return the new nice value.

Basic le input/output

type file_descr

The abstract type of le descriptors.

val stdin : file_descr

File descriptor for standard input.

val stdout : file_descr

File descriptor for standard output.

val stderr : file_descr

File descriptor for standard error.

type open_flag =
  | O_RDONLY

Open for reading

  | O_WRONLY

Open for writing

  | O_RDWR

Open for reading and writing

  | O_NONBLOCK

Open in non-blocking mode

  | O_APPEND

Open for append

  | O_CREAT

Create if nonexistent

  | O_TRUNC

Truncate to 0 length if existing

  | O_EXCL

Fail if existing

  | O_NOCTTY

Don't make this dev a controlling tty

  | O_DSYNC

Writes complete as `Synchronised I/O data integrity completion'

  | O_SYNC

Writes complete as `Synchronised I/O le integrity completion'

133

| O_RSYNC

       Reads complete as writes (depending on O_SYNC/O_DSYNC)

The ags to Unix.openfile [45].

type file_perm = int

    The type of le access rights, e.g. 0o640 is read and write for user, read for group, none for others

val openfile : string -> open_flag list -> file_perm -> file_descr

    Open the named le with the given ags. Third argument is the permissions to give to the le if it is created. Return a le descriptor on the named le.

val close : file_descr -> unit

    Close a le descriptor.

val read : file_descr -> string -> int -> int -> int

    read fd buff ofs len reads len characters from descriptor fd , storing them in string buff , starting at position ofs in string buff . Return the number of characters actually read.

val write : file_descr -> string -> int -> int -> int

    write fd buff ofs len writes len characters to descriptor fd , taking them from string buff , starting at position ofs in string buff . Return the number of characters actually written. write repeats the writing operation until all characters have been written or an error occurs.

val single_write : file_descr -> string -> int -> int -> int

    Same as write , but attempts to write only once. Thus, if an error occurs, single_write guarantees that no data has been written.

   Interfacing with the standard input/output library

val in_channel_of_descr : file_descr -> Pervasives.in_channel

    Create an input channel reading from the given descriptor. The channel is initially in binary mode; use set_binary_mode_in ic false if text mode is desired.

val out_channel_of_descr : file_descr -> Pervasives.out_channel

    Create an output channel writing on the given descriptor. The channel is initially in binary mode; use set_binary_mode_out oc false if text mode is desired.

val descr_of_in_channel : Pervasives.in_channel -> file_descr

    Return the descriptor corresponding to an input channel.

val descr_of_out_channel : Pervasives.out_channel -> file_descr

    Return the descriptor corresponding to an output channel.

Seeking and truncating

```
type  seek_command  =
   |  SEEK_SET
            indicates positions relative to the beginning of the  le

   |  SEEK_CUR
            indicates positions relative to the current position

   |  SEEK_END
            indicates positions relative to the end of the  le
         Positioning modes forUnix.lseek  [45].
```

```
val  lseek  :  file_descr  ->  int  ->  seek_command  ->  int
```
Set the current position for a le descriptor

```
val  truncate  :  string  ->  int  ->  unit
```
Truncates the named le to the given size.

```
val  ftruncate  :  file_descr  ->  int  ->  unit
```
Truncates the le corresponding to the given descriptor to the given size.

File status

```
type  file_kind  =
   |  S_REG
            Regular  le

   |  S_DIR
            Directory

   |  S_CHR
            Character device

   |  S_BLK
            Block device

   |  S_LNK
            Symbolic link

   |  S_FIFO
            Named pipe

   |  S_SOCK
            Socket

type  stats  =  {
   st_dev  :  int  ;
            Device number
```

st_ino : int ;

    Inode number

st_kind : file_kind ;

    Kind of the le

st_perm : file_perm ;

    Access rights

st_nlink : int ;

    Number of links

st_uid : int ;

    User id of the owner

st_gid : int ;

    Group ID of the le's group

st_rdev : int ;

    Device minor number

st_size : int ;

    Size in bytes

st_atime : float ;

    Last access time

st_mtime : float ;

    Last modi cation time

st_ctime : float ;

    Last status change time

}

    The information returned by the Unix.stat [45] calls.

val stat : string -> stats

    Return the information for the named le.

val lstat : string -> stats

    Same asUnix.stat [45], but in case the le is a symbolic link, return the information for the link itself.

val fstat : file_descr -> stats

    Return the information for the le associated with the given descriptor.

val isatty : file_descr -> bool

    Return true if the given le descriptor refers to a terminal or console window,false otherwise.

File operations on large les

module LargeFile :
  sig
      val lseek : Unix.file_descr -> int64 -> Unix.seek_command -> int64
      val truncate : string -> int64 -> unit
      val ftruncate : Unix.file_descr -> int64 -> unit
      type stats = {
        st_dev : int ;

                  Device number

        st_ino : int ;

                  Inode number

        st_kind : Unix.file_kind ;

                  Kind of the le

        st_perm : Unix.file_perm ;

                  Access rights

        st_nlink : int ;

                  Number of links

        st_uid : int ;

                  User id of the owner

        st_gid : int ;

                  Group ID of the le's group

        st_rdev : int ;

                  Device minor number

        st_size : int64 ;

                  Size in bytes

        st_atime : float ;

                  Last access time

        st_mtime : float ;

                  Last modi cation time

        st_ctime : float ;

                  Last status change time

```
        }
        val stat : string -> stats
        val lstat : string -> stats
        val fstat : Unix.file_descr -> stats
    end
```

File operations on large les. This sub-module provides 64-bit variants of the functions
Unix.lseek [45] (for positioning a le descriptor), Unix.truncate [45] and
Unix.ftruncate [45] (for changing the size of a le), andUnix.stat [45], Unix.lstat [45] and
Unix.fstat [45] (for obtaining information on les). These alternate functions represent
positions and sizes by 64-bit integers (typeint64) instead of regular integers (typeint),
thus allowing operating on les whose sizes are greater thanmax_int.

Operations on le names

```
val unlink : string -> unit
```

Removes the named le

```
val rename : string -> string -> unit
```

rename old newchanges the name of a le fromold to new.

```
val link : string -> string -> unit
```

link source dest creates a hard link nameddest to the le named source.

File permissions and ownership

```
type access_permission =
  | R_OK
```

Read permission

```
  | W_OK
```

Write permission

```
  | X_OK
```

Execution permission

```
  | F_OK
```

File exists

Flags for the Unix.access [45] call.

```
val chmod : string -> file_perm -> unit
```

Change the permissions of the named le.

```
val fchmod : file_descr -> file_perm -> unit
```

Change the permissions of an opened le.

```
val chown : string -> int -> int -> unit
```

Change the owner uid and owner gid of the named le.

val fchown : file_descr -> int -> int -> unit

Change the owner uid and owner gid of an opened le.

val umask : int -> int

Set the process's le mode creation mask, and return the previous mask.

val access : string -> access_permission list -> unit

Check that the process has the given permissions over the named le. Raise Unix_error otherwise.

Operations on le descriptors

val dup : file_descr -> file_descr

Return a new le descriptor referencing the same le as the given descriptor.

val dup2 : file_descr -> file_descr -> unit

dup2 fd1 fd2 duplicates fd1 to fd2, closing fd2 if already opened.

val set_nonblock : file_descr -> unit

Set the non-blocking ag on the given descriptor. When the non-blocking ag is set, reading on a descriptor on which there is temporarily no data available raises the EAGAIN or EWOULDBLOCK error instead of blocking; writing on a descriptor on which there is temporarily no room for writing also raises EAGAIN or EWOULDBLOCK.

val clear_nonblock : file_descr -> unit

Clear the non-blocking ag on the given descriptor. See Unix.set_nonblock [45].

val set_close_on_exec : file_descr -> unit

Set the close-on-exec ag on the given descriptor. A descriptor with the close-on-exec ag is automatically closed when the current process starts another program with one of the exec functions.

val clear_close_on_exec : file_descr -> unit

Clear the close-on-exec ag on the given descriptor. See Unix.set_close_on_exec [45].

Directories

val mkdir : string -> file_perm -> unit

Create a directory with the given permissions.

val rmdir : string -> unit

Remove an empty directory.

val chdir : string -> unit

Change the process working directory.

val getcwd : unit -> string

    Return the name of the current working directory.

val chroot : string -> unit

    Change the process root directory.

type dir_handle

    The type of descriptors over opened directories.

val opendir : string -> dir_handle

    Open a descriptor on a directory

val readdir : dir_handle -> string

    Return the next entry in a directory.

    Raises End_of_file when the end of the directory has been reached.

val rewinddir : dir_handle -> unit

    Reposition the descriptor to the beginning of the directory

val closedir : dir_handle -> unit

    Close a directory descriptor.

  Pipes and redirections

val pipe : unit -> file_descr * file_descr

    Create a pipe. The rst component of the result is opened for reading, that's the exit to the pipe. The second component is opened for writing, that's the entrance to the pipe.

val mkfifo : string -> file_perm -> unit

    Create a named pipe with the given permissions.

  High-level process and redirection management

val create_process :
  string ->
  string array -> file_descr -> file_descr -> file_descr -> int

    create_process prog args new_stdin new_stdout new_stderr forks a new process that executes the program in le prog, with arguments args . The pid of the new process is returned immediately; the new process executes concurrently with the current process. The standard input and outputs of the new process are connected to the descriptors new_stdin , new_stdout and new_stderr . Passing e.g. stdout for new_stdout prevents the redirection and causes the new process to have the same standard output as the current process. The executable le prog is searched in the path. The new process has the same environment as the current process.

val create_process_env :
  string ->
  string array ->
  string array -> file_descr -> file_descr -> file_descr -> int

> create_process_env prog args env new_stdin new_stdout new_stderr   works as
> Unix.create_process [45], except that the extra argument env speci es the environment
> passed to the program.

val open_process_in : string -> Pervasives.in_channel

> High-level pipe and process management. This function runs the given command in parallel
> with the program. The standard output of the command is redirected to a pipe, which can
> be read via the returned input channel. The command is interpreted by the shell /bin/sh
> (cf. system).

val open_process_out : string -> Pervasives.out_channel

> Same as Unix.open_process_in [45], but redirect the standard input of the command to a
> pipe. Data written to the returned output channel is sent to the standard input of the
> command. Warning: writes on output channels are bu ered, hence be careful to call
> Pervasives.flush   [30] at the right times to ensure correct synchronization.

val open_process : string -> Pervasives.in_channel * Pervasives.out_channel

> Same as Unix.open_process_out [45], but redirects both the standard input and standard
> output of the command to pipes connected to the two returned channels. The input channel
> is connected to the output of the command, and the output channel to the input of the
> command.

val open_process_full :
  string ->
  string array ->
  Pervasives.in_channel * Pervasives.out_channel * Pervasives.in_channel

> Similar to Unix.open_process [45], but the second argument speci es the environment
> passed to the command. The result is a triple of channels connected respectively to the
> standard output, standard input, and standard error of the command.

val close_process_in : Pervasives.in_channel -> process_status

> Close channels opened by Unix.open_process_in [45], wait for the associated command to
> terminate, and return its termination status.

val close_process_out : Pervasives.out_channel -> process_status

> Close channels opened by Unix.open_process_out [45], wait for the associated command to
> terminate, and return its termination status.

val close_process :
  Pervasives.in_channel * Pervasives.out_channel -> process_status

Close channels opened by Unix.open_process [45], wait for the associated command to terminate, and return its termination status.

val close_process_full :
  Pervasives.in_channel * Pervasives.out_channel * Pervasives.in_channel ->
  process_status

Close channels opened by Unix.open_process_full [45], wait for the associated command to terminate, and return its termination status.

Symbolic links

val symlink : string -> string -> unit

symlink source dest creates the file dest as a symbolic link to the file source.

val readlink : string -> string

Read the contents of a link.

Polling

val select :
  file_descr list ->
  file_descr list ->
  file_descr list ->
  float -> file_descr list * file_descr list * file_descr list

Wait until some input/output operations become possible on some channels. The three list arguments are, respectively, a set of descriptors to check for reading (rst argument), for writing (second argument), or for exceptional conditions (third argument). The fourth argument is the maximal timeout, in seconds; a negative fourth argument means no timeout (unbounded wait). The result is composed of three sets of descriptors: those ready for reading (rst component), ready for writing (second component), and over which an exceptional condition is pending (third component).

Locking

type lock_command =
  | F_ULOCK

      Unlock a region

  | F_LOCK

      Lock a region for writing, and block if already locked

  | F_TLOCK

      Lock a region for writing, or fail if already locked

  | F_TEST

      Test a region for other process locks

  | F_RLOCK

      Lock a region for reading, and block if already locked

| F_TRLOCK

       Lock a region for reading, or fail if already locked

    Commands for Unix.lockf [45].

val lockf : file_descr -> lock_command -> int -> unit

    lockf fd cmd size puts a lock on a region of the le opened as fd . The region starts at the current read/write position for fd (as set by Unix.lseek [45]), and extends size bytes forward if size is positive, size bytes backwards if size is negative, or to the end of the le if size is zero. A write lock prevents any other process from acquiring a read or write lock on the region. A read lock prevents any other process from acquiring a write lock on the region, but lets other processes acquire read locks on it.

    The F_LOCK and F_TLOCK commands attempts to put a write lock on the speci ed region. The F_RLOCK and F_TRLOCK commands attempts to put a read lock on the speci ed region. If one or several locks put by another process prevent the current process from acquiring the lock, F_LOCK and F_RLOCK block until these locks are removed, while F_TLOCK and F_TRLOCK fail immediately with an exception. The F_ULOCK removes whatever locks the current process has on the speci ed region. Finally, the F_TEST command tests whether a write lock can be acquired on the speci ed region, without actually putting a lock. It returns immediately if successful, or fails otherwise.

    Signals Note: installation of signal handlers is performed via the functions Sys.signal [43] and Sys.set_signal [43].

val kill : int -> int -> unit

    kill pid sig sends signal number sig to the process with id pid .

type sigprocmask_command =
  | SIG_SETMASK
  | SIG_BLOCK
  | SIG_UNBLOCK

val sigprocmask : sigprocmask_command -> int list -> int list

    sigprocmask cmd sigs changes the set of blocked signals. If cmd is SIG_SETMASK, blocked signals are set to those in the list sigs . If cmd is SIG_BLOCK, the signals in sigs are added to the set of blocked signals. If cmd is SIG_UNBLOCK, the signals in sigs are removed from the set of blocked signals. sigprocmask returns the set of previously blocked signals.

val sigpending : unit -> int list

    Return the set of blocked signals that are currently pending.

val sigsuspend : int list -> unit

    sigsuspend sigs atomically sets the blocked signals to sigs and waits for a non-ignored, non-blocked signal to be delivered. On return, the blocked signals are reset to their initial value.

val pause : unit -> unit

Wait until a non-ignored, non-blocked signal is delivered.

Time functions

```
type process_times = {
  tms_utime : float ;
          User time for the process
  tms_stime : float ;
          System time for the process
  tms_cutime : float ;
          User time for the children processes
  tms_cstime : float ;
          System time for the children processes
}
```

The execution times (CPU times) of a process.

```
type tm = {
  tm_sec : int ;
          Seconds 0..60
  tm_min : int ;
          Minutes 0..59
  tm_hour : int ;
          Hours 0..23
  tm_mday : int ;
          Day of month 1..31
  tm_mon : int ;
          Month of year 0..11
  tm_year : int ;
          Year - 1900
  tm_wday : int ;
          Day of week (Sunday is 0)
  tm_yday : int ;
          Day of year 0..365
  tm_isdst : bool ;
          Daylight time savings in e ect
}
```

The type representing wallclock time and calendar date.

```
val time : unit -> float
```

Return the current time since 00:00:00 GMT, Jan. 1, 1970, in seconds.

val gettimeofday : unit -> float

Same as Unix.time [45], but with resolution better than 1 second.

val gmtime : float -> tm

Convert a time in seconds, as returned by Unix.time [45], into a date and a time. Assumes UTC (Coordinated Universal Time), also known as GMT.

val localtime : float -> tm

Convert a time in seconds, as returned by Unix.time [45], into a date and a time. Assumes the local time zone.

val mktime : tm -> float * tm

Convert a date and time, specied by the tm argument, into a time in seconds, as returned by Unix.time [45]. The tm_isdst , tm_wday and tm_yday elds of tm are ignored. Also return a normalized copy of the given tm record, with the tm_wday, tm_yday, and tm_isdst elds recomputed from the other elds, and the other elds normalized (so that, e.g., 40 October is changed into 9 November). The tm argument is interpreted in the local time zone.

val alarm : int -> int

Schedule a SIGALRM signal after the given number of seconds.

val sleep : int -> unit

Stop execution for the given number of seconds.

val times : unit -> process_times

Return the execution times of the process.

val utimes : string -> float -> float -> unit

Set the last access time (second arg) and last modication time (third arg) for a le. Times are expressed in seconds from 00:00:00 GMT, Jan. 1, 1970. A time of 0.0 is interpreted as the current time.

type interval_timer =
  | ITIMER_REAL

         decrements in real time, and sends the signal SIGALRM when expired.

  | ITIMER_VIRTUAL

         decrements in process virtual time, and sends SIGVTALRM when expired.

  | ITIMER_PROF

         (for proling) decrements both when the process is running and when the system is running on behalf of the process; it sends SIGPROF when expired.

The three kinds of interval timers.

```
type  interval_timer_status = {
   it_interval : float ;
              Period
   it_value : float ;
              Current value of the timer
}
```
The type describing the status of an interval timer

```
val  getitimer : interval_timer -> interval_timer_status
```
Return the current status of the given interval timer.

```
val  setitimer :
   interval_timer ->
   interval_timer_status -> interval_timer_status
```
setitimer t s sets the interval timer t and returns its previous status. The s argument is interpreted as follows: s.it_value , if nonzero, is the time to the next timer expiration; s.it_interval , if nonzero, speci es a value to be used in reloading it_value when the timer expires. Settings.it_value to zero disable the timer. Settings.it_interval to zero causes the timer to be disabled after its next expiration.

   User id, group id
```
val  getuid : unit -> int
```
Return the user id of the user executing the process.

```
val  geteuid : unit -> int
```
Return the e ective user id under which the process runs.

```
val  setuid : int -> unit
```
Set the real user id and e ective user id for the process.

```
val  getgid : unit -> int
```
Return the group id of the user executing the process.

```
val  getegid : unit -> int
```
Return the e ective group id under which the process runs.

```
val  setgid : int -> unit
```
Set the real group id and e ective group id for the process.

```
val  getgroups : unit -> int array
```
Return the list of groups to which the user executing the process belongs.

```
val  setgroups : int array -> unit
```

setgroups groups sets the supplementary group IDs for the calling process. Appropriate privileges are required.

val initgroups : string -> int -> unit

initgroups user group initializes the group access list by reading the group database /etc/group and using all groups of which user is a member. The additional groupgroup is also added to the list.

```
type passwd_entry = {
  pw_name : string ;
  pw_passwd : string ;
  pw_uid : int ;
  pw_gid : int ;
  pw_gecos : string ;
  pw_dir : string ;
  pw_shell : string ;
}
```

Structure of entries in the passwddatabase.

```
type group_entry = {
  gr_name : string ;
  gr_passwd : string ;
  gr_gid : int ;
  gr_mem : string array ;
}
```

Structure of entries in the groups database.

val getlogin : unit -> string

Return the login name of the user executing the process.

val getpwnam : string -> passwd_entry

Find an entry in passwdwith the given name, or raiseNot_found.

val getgrnam : string -> group_entry

Find an entry in group with the given name, or raiseNot_found.

val getpwuid : int -> passwd_entry

Find an entry in passwdwith the given user id, or raiseNot_found.

val getgrgid : int -> group_entry

Find an entry in group with the given group id, or raise Not_found.

Internet addresses

type inet_addr

The abstract type of Internet addresses.

val inet_addr_of_string : string -> inet_addr

>   Conversion from the printable representation of an Internet address to its internal
>   representation. The argument string consists of 4 numbers separated by periods
>   (XXX.YYY.ZZZ.TTT) for IPv4 addresses, and up to 8 numbers separated by colons for IPv6
>   addresses. Raise Failure when given a string that does not match these formats.

val string_of_inet_addr : inet_addr -> string

>   Return the printable representation of the given Internet address. See
>   Unix.inet_addr_of_string [45] for a description of the printable representation.

val inet_addr_any : inet_addr

>   A special IPv4 address, for use only with bind , representing all the Internet addresses that
>   the host machine possesses.

val inet_addr_loopback : inet_addr

>   A special IPv4 address representing the host machine (127.0.0.1).

val inet6_addr_any : inet_addr

>   A special IPv6 address, for use only with bind , representing all the Internet addresses that
>   the host machine possesses.

val inet6_addr_loopback : inet_addr

>   A special IPv6 address representing the host machine (::1).

   Sockets

type socket_domain =
  | PF_UNIX

>   Unix domain

  | PF_INET

>   Internet domain (IPv4)

  | PF_INET6

>   Internet domain (IPv6)

>   The type of socket domains. Not all platforms support IPv6 sockets (type PF_INET6).

type socket_type =
  | SOCK_STREAM

>   Stream socket

  | SOCK_DGRAM

>   Datagram socket

  | SOCK_RAW

>   Raw socket

  | SOCK_SEQPACKET

Sequenced packets socket

The type of socket kinds, specifying the semantics of communications.

type sockaddr =
  | ADDR_UNIX of string
  | ADDR_INET of inet_addr * int

The type of socket addresses. ADDR_UNIX name is a socket address in the Unix domain; name is a file name in the file system. ADDR_INET(addr,port) is a socket address in the Internet domain; addr is the Internet address of the machine, and port is the port number.

val socket : socket_domain -> socket_type -> int -> file_descr

Create a new socket in the given domain, and with the given kind. The third argument is the protocol type; 0 selects the default protocol for that kind of sockets.

val domain_of_sockaddr : sockaddr -> socket_domain

Return the socket domain adequate for the given socket address.

val socketpair :
  socket_domain ->
  socket_type -> int -> file_descr * file_descr

Create a pair of unnamed sockets, connected together.

val accept : file_descr -> file_descr * sockaddr

Accept connections on the given socket. The returned descriptor is a socket connected to the client; the returned address is the address of the connecting client.

val bind : file_descr -> sockaddr -> unit

Bind a socket to an address.

val connect : file_descr -> sockaddr -> unit

Connect a socket to an address.

val listen : file_descr -> int -> unit

Set up a socket for receiving connection requests. The integer argument is the maximal number of pending requests.

type shutdown_command =
  | SHUTDOWN_RECEIVE

Close for receiving

  | SHUTDOWN_SEND

Close for sending

  | SHUTDOWN_ALL

Close both

149

The type of commands for shutdown.

val shutdown : file_descr -> shutdown_command -> unit

Shutdown a socket connection. SHUTDOWN_SEND as second argument causes reads on the other end of the connection to return an end-of- le condition. SHUTDOWN_RECEIVE causes writes on the other end of the connection to return a closed pipe condition (SIGPIPE signal).

val getsockname : file_descr -> sockaddr

Return the address of the given socket.

val getpeername : file_descr -> sockaddr

Return the address of the host connected to the given socket.

type msg_flag =
  | MSG_OOB
  | MSG_DONTROUTE
  | MSG_PEEK

The ags for Unix.recv [45], Unix.recvfrom [45], Unix.send [45] and Unix.sendto [45].

val recv : file_descr -> string -> int -> int -> msg_flag list -> int

Receive data from a connected socket.

val recvfrom :
  file_descr ->
  string -> int -> int -> msg_flag list -> int * sockaddr

Receive data from an unconnected socket.

val send : file_descr -> string -> int -> int -> msg_flag list -> int

Send data over a connected socket.

val sendto :
  file_descr ->
  string -> int -> int -> msg_flag list -> sockaddr -> int

Send data over an unconnected socket.

Socket options

type socket_bool_option =
  | SO_DEBUG

Record debugging information

  | SO_BROADCAST

Permit sending of broadcast messages

  | SO_REUSEADDR

Allow reuse of local addresses for bind

  | SO_KEEPALIVE

150

Keep connection active

| SO_DONTROUTE

Bypass the standard routing algorithms

| SO_OOBINLINE

Leave out-of-band data in line

| SO_ACCEPTCONN

Report whether socket listening is enabled

| TCP_NODELAY

Control the Nagle algorithm for TCP sockets

| IPV6_ONLY

Forbid binding an IPv6 socket to an IPv4 address

The socket options that can be consulted with Unix.getsockopt [45] and modi ed with Unix.setsockopt [45]. These options have a boolean (true / false) value.

type socket_int_option =
| SO_SNDBUF

Size of send bu er

| SO_RCVBUF

Size of received bu er

| SO_ERROR

Deprecated. Use Unix.getsockopt_error [45] instead.

| SO_TYPE

Report the socket type

| SO_RCVLOWAT

Minimum number of bytes to process for input operations

| SO_SNDLOWAT

Minimum number of bytes to process for output operations

The socket options that can be consulted with Unix.getsockopt_int [45] and modi ed with Unix.setsockopt_int [45]. These options have an integer value.

type socket_optint_option =
| SO_LINGER

Whether to linger on closed connections that have data present, and for how long (in seconds)

The socket options that can be consulted with Unix.getsockopt_optint [45] and modi ed with Unix.setsockopt_optint [45]. These options have a value of type int option , with None meaning disabled .

type socket_float_option =
  | SO_RCVTIMEO

        Timeout for input operations

  | SO_SNDTIMEO

        Timeout for output operations

    The socket options that can be consulted withUnix.getsockopt_float   [45] and modi ed
    with Unix.setsockopt_float   [45]. These options have a oating-point value representing a
    time in seconds. The value 0 means in nite timeout.

val getsockopt : file_descr -> socket_bool_option -> bool
    Return the current status of a boolean-valued option in the given socket.

val setsockopt : file_descr -> socket_bool_option -> bool -> unit
    Set or clear a boolean-valued option in the given socket.

val getsockopt_int : file_descr -> socket_int_option -> int
    Same asUnix.getsockopt [45] for an integer-valued socket option.

val setsockopt_int : file_descr -> socket_int_option -> int -> unit
    Same asUnix.setsockopt [45] for an integer-valued socket option.

val getsockopt_optint : file_descr -> socket_optint_option -> int option
    Same asUnix.getsockopt [45] for a socket option whose value is a int option   .

val setsockopt_optint :
  file_descr -> socket_optint_option -> int option -> unit
    Same asUnix.setsockopt [45] for a socket option whose value is a int option   .

val getsockopt_float : file_descr -> socket_float_option -> float
    Same asUnix.getsockopt [45] for a socket option whose value is a oating-point number.

val setsockopt_float : file_descr -> socket_float_option -> float -> unit
    Same asUnix.setsockopt [45] for a socket option whose value is a oating-point number.

val getsockopt_error : file_descr -> error option
    Return the error condition associated with the given socket, and clear it.

  High-level network connection functions

val open_connection :
  sockaddr -> Pervasives.in_channel * Pervasives.out_channel
    Connect to a server at the given address. Return a pair of bu ered channels connected to
    the server. Remember to callPervasives.flush   [30] on the output channel at the right
    times to ensure correct synchronization.

val shutdown_connection : Pervasives.in_channel -> unit

     Shut down a connection established withUnix.open_connection [45]; that is, transmit an end-of- le condition to the server reading on the other side of the connection.

val establish_server :
  (Pervasives.in_channel -> Pervasives.out_channel -> unit) ->
  sockaddr -> unit

     Establish a server on the given address. The function given as rst argument is called for each connection with two bu ered channels connected to the client. A new process is created for each connection. The functionUnix.establish_server [45] never returns normally.

  Host and protocol databases

type host_entry = {
  h_name : string ;
  h_aliases : string array ;
  h_addrtype : socket_domain ;
  h_addr_list : inet_addr array ;
}

     Structure of entries in the hosts database.

type protocol_entry = {
  p_name : string ;
  p_aliases : string array ;
  p_proto : int ;
}

     Structure of entries in the protocols database.

type service_entry = {
  s_name : string ;
  s_aliases : string array ;
  s_port : int ;
  s_proto : string ;
}

     Structure of entries in the services database.

val gethostname : unit -> string

     Return the name of the local host.

val gethostbyname : string -> host_entry

     Find an entry in hosts with the given name, or raiseNot_found.

val gethostbyaddr : inet_addr -> host_entry

     Find an entry in hosts with the given address, or raiseNot_found.

val getprotobyname : string -> protocol_entry

153

Find an entry in protocols with the given name, or raise Not_found.

val getprotobynumber : int -> protocol_entry

Find an entry in protocols with the given protocol number, or raise Not_found.

val getservbyname : string -> string -> service_entry

Find an entry in services with the given name, or raise Not_found.

val getservbyport : int -> string -> service_entry

Find an entry in services with the given service number, or raise Not_found.

```
type addr_info = {
  ai_family : socket_domain ;
```
        Socket domain
```
  ai_socktype : socket_type ;
```
        Socket type
```
  ai_protocol : int ;
```
        Socket protocol number
```
  ai_addr : sockaddr ;
```
        Address
```
  ai_canonname : string ;
```
        Canonical host name
```
}
```
        Address information returned by Unix.getaddrinfo [45].

```
type getaddrinfo_option =
  | AI_FAMILY of socket_domain
```
        Impose the given socket domain
```
  | AI_SOCKTYPE of socket_type
```
        Impose the given socket type
```
  | AI_PROTOCOL of int
```
        Impose the given protocol
```
  | AI_NUMERICHOST
```
        Do not call name resolver, expect numeric IP address
```
  | AI_CANONNAME
```
        Fill the ai_canonname field of the result
```
  | AI_PASSIVE
```
        Set address to any address for use with Unix.bind [45]
        Options to Unix.getaddrinfo [45].

val getaddrinfo :
  string -> string -> getaddrinfo_option list -> addr_info list

    getaddrinfo host service opts   returns a list of Unix.addr_info [45] records describing socket parameters and addresses suitable for communicating with the given host and service. The empty list is returned if the host or service names are unknown, or the constraints expressed in opts cannot be satis ed.

    host is either a host name or the string representation of an IP address. host can be given as the empty string; in this case, the any address or the loopback address are used, depending whether opts contains AI_PASSIVE. service is either a service name or the string representation of a port number. service can be given as the empty string; in this case, the port eld of the returned addresses is set to 0. opts is a possibly empty list of options that allows the caller to force a particular socket domain (e.g. IPv6 only or IPv4 only) or a particular socket type (e.g. TCP only or UDP only).

type name_info = {
  ni_hostname : string ;
       Name or IP address of host

  ni_service : string ;
}
    Name of service or port number

  Host and service information returned by Unix.getnameinfo [45].

type getnameinfo_option =
  | NI_NOFQDN
       Do not qualify local host names

  | NI_NUMERICHOST
       Always return host as IP address

  | NI_NAMEREQD
       Fail if host name cannot be determined

  | NI_NUMERICSERV
       Always return service as port number

  | NI_DGRAM
       Consider the service as UDP-based instead of the default TCP
    Options to Unix.getnameinfo [45].

val getnameinfo : sockaddr -> getnameinfo_option list -> name_info
    getnameinfo addr opts returns the host name and service name corresponding to the socket address addr. opts is a possibly empty list of options that governs how these names are obtained. Raise Not_found if an error occurs.

Terminal interface

The following functions implement the POSIX standard terminal interface. They provide control over asynchronous communication ports and pseudo-terminals. Refer to the `termios` man page for a complete description.

```
type terminal_io = {
  mutable c_ignbrk : bool ;
          Ignore the break condition.

  mutable c_brkint : bool ;
          Signal interrupt on break condition.

  mutable c_ignpar : bool ;
          Ignore characters with parity errors.

  mutable c_parmrk : bool ;
          Mark parity errors.

  mutable c_inpck : bool ;
          Enable parity check on input.

  mutable c_istrip : bool ;
          Strip 8th bit on input characters.

  mutable c_inlcr : bool ;
          Map NL to CR on input.

  mutable c_igncr : bool ;
          Ignore CR on input.

  mutable c_icrnl : bool ;
          Map CR to NL on input.

  mutable c_ixon : bool ;
          Recognize XON/XOFF characters on input.

  mutable c_ixoff : bool ;
          Emit XON/XOFF chars to control input  ow.

  mutable c_opost : bool ;
          Enable output processing.

  mutable c_obaud : int ;
          Output baud rate (0 means close connection).

  mutable c_ibaud : int ;
          Input baud rate.

  mutable c_csize : int ;
          Number of bits per character (5-8).

  mutable c_cstopb : int ;
```

Number of stop bits (1-2).

mutable c_cread : bool ;
      Reception is enabled.

mutable c_parenb : bool ;
      Enable parity generation and detection.

mutable c_parodd : bool ;
      Specify odd parity instead of even.

mutable c_hupcl : bool ;
      Hang up on last close.

mutable c_clocal : bool ;
      Ignore modem status lines.

mutable c_isig : bool ;
      Generate signal on INTR, QUIT, SUSP.

mutable c_icanon : bool ;
      Enable canonical processing (line bu ering and editing)

mutable c_noflsh : bool ;
      Disable ush after INTR, QUIT, SUSP.

mutable c_echo : bool ;
      Echo input characters.

mutable c_echoe : bool ;
      Echo ERASE (to erase previous character).

mutable c_echok : bool ;
      Echo KILL (to erase the current line).

mutable c_echonl : bool ;
      Echo NL even if c_echo is not set.

mutable c_vintr : char ;
      Interrupt character (usually ctrl-C).

mutable c_vquit : char ;
      Quit character (usually ctrl-\).

mutable c_verase : char ;
      Erase character (usually DEL or ctrl-H).

mutable c_vkill : char ;
      Kill line character (usually ctrl-U).

mutable c_veof : char ;
      End-of- le character (usually ctrl-D).

mutable c_veol : char ;

>   Alternate end-of-line char. (usually none).

mutable c_vmin : int ;

>   Minimum number of characters to read before the read request is satis ed.

mutable c_vtime : int ;

>   Maximum read wait (in 0.1s units).

mutable c_vstart : char ;

>   Start character (usually ctrl-Q).

mutable c_vstop : char ;

>   Stop character (usually ctrl-S).

}

val tcgetattr : file_descr -> terminal_io

>   Return the status of the terminal referred to by the given le descriptor.

type setattr_when =
  | TCSANOW
  | TCSADRAIN
  | TCSAFLUSH

val tcsetattr : file_descr -> setattr_when -> terminal_io -> unit

>   Set the status of the terminal referred to by the given le descriptor. The second argument indicates when the status change takes place: immediately (TCSANOW), when all pending output has been transmitted (TCSADRAIN), or after ushing all input that has been received but not read (TCSAFLUSH). TCSADRAIN is recommended when changing the output parameters; TCSAFLUSH, when changing the input parameters.

val tcsendbreak : file_descr -> int -> unit

>   Send a break condition on the given le descriptor. The second argument is the duration of the break, in 0.1s units; 0 means standard duration (0.25s).

val tcdrain : file_descr -> unit

>   Waits until all output written on the given le descriptor has been transmitted.

type flush_queue =
  | TCIFLUSH
  | TCOFLUSH
  | TCIOFLUSH

val tcflush : file_descr -> flush_queue -> unit

>   Discard data written on the given le descriptor but not yet transmitted, or data received but not yet read, depending on the second argument: TCIFLUSH ushes data received but not read, TCOFLUSH ushes data written but not transmitted, and TCIOFLUSH ushes both.

```
type flow_action =
  | TCOOFF
  | TCOON
  | TCIOFF
  | TCION
```

val tcflow : file_descr -> flow_action -> unit

Suspend or restart reception or transmission of data on the given le descriptor, depending on the second argument:TCOOFF suspends output,TCOON restarts output, TCIOFF transmits a STOP character to suspend input, andTCION transmits a START character to restart input.

val setsid : unit -> int

Put the calling process in a new session and detach it from its controlling terminal.

46 Module Str : Regular expressions and high-level string processing

Regular expressions

type regexp

The type of compiled regular expressions.

val regexp : string -> regexp

Compile a regular expression. The following constructs are recognized:

- .   Matches any character except newline.
- *   (post x) Matches the preceding expression zero, one or several times
- +   (post x) Matches the preceding expression one or several times
- ?   (post x) Matches the preceding expression once or not at all
- [..]   Character set. Ranges are denoted with - , as in [a-z] . An initial ^, as in [^0-9] , complements the set. To include a] character in a set, make it the rst character of the set. To include a - character in a set, make it the rst or the last character of the set.
- ^ Matches at beginning of line (either at the beginning of the matched string, or just after a newline character).
- $ Matches at end of line (either at the end of the matched string, or just before a newline character).
- \| (in x) Alternative between two expressions.
- \(..\)   Grouping and naming of the enclosed expression.
- \1   The text matched by the rst \(...\)   expression (\2 for the second expression, and so on up to\9).
- \b   Matches word boundaries.

- \ Quotes special characters. The special characters are $ ^ . * + ? [] .

val regexp_case_fold : string -> regexp

> Same as regexp, but the compiled expression will match text in a case-insensitive way: uppercase and lowercase letters will be considered equivalent.

val quote : string -> string

> Str.quote s returns a regexp string that matches exactly s and nothing else.

val regexp_string : string -> regexp

> Str.regexp_string s returns a regular expression that matches exactly s and nothing else.

val regexp_string_case_fold : string -> regexp

> Str.regexp_string_case_fold is similar to Str.regexp_string [46], but the regexp matches in a case-insensitive way.

String matching and searching

val string_match : regexp -> string -> int -> bool

> string_match r s start tests whether a substring of s that starts at position start matches the regular expression r. The first character of a string has position 0, as usual.

val search_forward : regexp -> string -> int -> int

> search_forward r s start searches the string s for a substring matching the regular expression r. The search starts at position start and proceeds towards the end of the string. Return the position of the first character of the matched substring, or raise Not_found if no substring matches.

val search_backward : regexp -> string -> int -> int

> search_backward r s last searches the string s for a substring matching the regular expression r. The search first considers substrings that start at position last and proceeds towards the beginning of string. Return the position of the first character of the matched substring; raise Not_found if no substring matches.

val string_partial_match : regexp -> string -> int -> bool

> Similar to Str.string_match [46], but also returns true if the argument string is a prefix of a string that matches. This includes the case of a true complete match.

val matched_string : string -> string

> matched_string s returns the substring of s that was matched by the latest Str.string_match [46], Str.search_forward [46] or Str.search_backward [46]. The user must make sure that the parameter s is the same string that was passed to the matching or searching function.

val match_beginning : unit -> int

match_beginning() returns the position of the first character of the substring that was matched by Str.string_match [46], Str.search_forward [46] or Str.search_backward [46].

val match_end : unit -> int

match_end() returns the position of the character following the last character of the substring that was matched by string_match , search_forward or search_backward.

val matched_group : int -> string -> string

matched_group n s returns the substring of s that was matched by the nth group \(...\) of the regular expression during the latest Str.string_match [46], Str.search_forward [46] or Str.search_backward [46]. The user must make sure that the parameter s is the same string that was passed to the matching or searching function. matched_group n s raises Not_found if the nth group of the regular expression was not matched. This can happen with groups inside alternatives \| , options ? or repetitions * . For instance, the empty string will match \(a\)* , but matched_group 1 "" will raise Not_found because the first group itself was not matched.

val group_beginning : int -> int

group_beginning n returns the position of the first character of the substring that was matched by the nth group of the regular expression.

Raises

- Not_found if the nth group of the regular expression was not matched.

- Invalid_argument if there are fewer than n groups in the regular expression.

val group_end : int -> int

group_end n returns the position of the character following the last character of substring that was matched by the nth group of the regular expression.

Raises

- Not_found if the nth group of the regular expression was not matched.

- Invalid_argument if there are fewer than n groups in the regular expression.

Replacement

val global_replace : regexp -> string -> string -> string

global_replace regexp templ s returns a string identical to s, except that all substrings of s that match regexp have been replaced by templ . The replacement template templ can contain \1 , \2 , etc; these sequences will be replaced by the text matched by the corresponding group in the regular expression. \0 stands for the text matched by the whole regular expression.

val replace_first : regexp -> string -> string -> string

Same as Str.global_replace [46], except that only the first substring matching the regular expression is replaced.

val global_substitute : regexp -> (string -> string) -> string -> string

> global_substitute regexp subst s   returns a string identical to s, except that all substrings of s that match regexp have been replaced by the result of function subst . The function subst is called once for each matching substring, and receives s (the whole text) as argument.

val substitute_first : regexp -> (string -> string) -> string -> string

> Same as Str.global_substitute [46], except that only the first substring matching the regular expression is replaced.

val replace_matched : string -> string -> string

> replace_matched repl s returns the replacement text repl in which \1 , \2 , etc. have been replaced by the text matched by the corresponding groups in the most recent matching operation. s must be the same string that was matched during this matching operation.

Splitting

val split : regexp -> string -> string list

> split r s   splits s into substrings, taking as delimiters the substrings that match r , and returns the list of substrings. For instance, split (regexp "[\t]+") s   splits s into blank-separated words. An occurrence of the delimiter at the beginning and at the end of the string is ignored.

val bounded_split : regexp -> string -> int -> string list

> Same as Str.split [46], but splits into at most n substrings, where n is the extra integer parameter.

val split_delim : regexp -> string -> string list

> Same as Str.split [46] but occurrences of the delimiter at the beginning and at the end of the string are recognized and returned as empty strings in the result. For instance, split_delim (regexp " ") " abc "   returns [""; "abc"; ""]   , while split with the same arguments returns ["abc"] .

val bounded_split_delim : regexp -> string -> int -> string list

> Same as Str.bounded_split [46], but occurrences of the delimiter at the beginning and at the end of the string are recognized and returned as empty strings in the result.

type split_result =
  | Text of string
  | Delim of string

val full_split : regexp -> string -> split_result list

> Same as Str.split_delim [46], but returns the delimiters as well as the substrings contained between delimiters. The former are tagged Delim in the result list; the latter are tagged Text . For instance, full_split (regexp "[{}]") "{ab}"   returns [Delim "{"; Text "ab"; Delim "}"] .

val bounded_full_split : regexp -> string -> int -> split_result list

> Same as Str.bounded_split_delim [46], but returns the delimiters as well as the substrings contained between delimiters. The former are tagged Delim in the result list; the latter are tagged Text.

Extracting substrings

val string_before : string -> int -> string

> string_before s n returns the substring of all characters of s that precede position n (excluding the character at position n).

val string_after : string -> int -> string

> string_after s n returns the substring of all characters of s that follow position n (including the character at position n).

val first_chars : string -> int -> string

> first_chars s n returns the first n characters of s. This is the same function as Str.string_before [46].

val last_chars : string -> int -> string

> last_chars s n returns the last n characters of s.

47 Module Bigarray : Large, multi-dimensional, numerical arrays.

This module implements multi-dimensional arrays of integers and floating-point numbers, thereafter referred to as big arrays. The implementation allows efficient sharing of large numerical arrays between Caml code and C or Fortran numerical libraries.

Concerning the naming conventions, users of this module are encouraged to open Bigarray in their source, then refer to array types and operations via short dot notation, e.g. Array1.t or Array2.sub.

Big arrays support all the Caml ad-hoc polymorphic operations:

- comparisons (=, <>, <=, etc, as well as Pervasives.compare [30]);

- hashing (module Hash);

- and structured input-output (Pervasives.output_value [30] and Pervasives.input_value [30], as well as the functions from the Marshal [24] module).

Element kinds
Big arrays can contain elements of the following kinds:

- IEEE single precision (32 bits) floating-point numbers (Bigarray.float32_elt [47]),

- IEEE double precision (64 bits) floating-point numbers (Bigarray.float64_elt [47]),

- IEEE single precision (2 * 32 bits) floating-point complex numbers (Bigarray.complex32_elt [47]),

- IEEE double precision (2 * 64 bits) oating-point complex numbers (Bigarray.complex64_elt [47]),

- 8-bit integers (signed or unsigned) (Bigarray.int8_signed_elt [47] or Bigarray.int8_unsigned_elt [47]

- 16-bit integers (signed or unsigned) (Bigarray.int16_signed_elt [47] or Bigarray.int16_unsigned_elt [

- Caml integers (signed, 31 bits on 32-bit architectures, 63 bits on 64-bit architectures) (Bigarray.int_elt [4

- 32-bit signed integer (Bigarray.int32_elt [47]),

- 64-bit signed integers (Bigarray.int64_elt [47]),

- platform-native signed integers (32 bits on 32-bit architectures, 64 bits on 64-bit architectures) (Bigarray.nativeint_elt [47]).

Each element kind is represented at the type level by one of the abstract types de ned below.

type float32_elt

type float64_elt

type complex32_elt

type complex64_elt

type int8_signed_elt

type int8_unsigned_elt

type int16_signed_elt

type int16_unsigned_elt

type int_elt

type int32_elt

type int64_elt

type nativeint_elt

type ('a, 'b) kind

>To each element kind is associated a Caml type, which is the type of Caml values that can be stored in the big array or read back from it. This type is not necessarily the same as the type of the array elements proper: for instance, a big array whose elements are of kind float32_elt contains 32-bit single precision oats, but reading or writing one of its elements from Caml uses the Caml type float, which is 64-bit double precision oats.

>The abstract type ('a, 'b) kind captures this association of a Caml type 'a for values read or written in the big array, and of an element kind 'b which represents the actual contents of the big array. The following prede ned values of type kind list all possible associations of Caml types with element kinds:

val float32 : (float, float32_elt) kind

>See Bigarray.char [47].

val float64 : (float, float64_elt) kind

>See Bigarray.char [47].

val complex32 : (Complex.t, complex32_elt) kind

> See Bigarray.char [47].

val complex64 : (Complex.t, complex64_elt) kind

> See Bigarray.char [47].

val int8_signed : (int, int8_signed_elt) kind

> See Bigarray.char [47].

val int8_unsigned : (int, int8_unsigned_elt) kind

> See Bigarray.char [47].

val int16_signed : (int, int16_signed_elt) kind

> See Bigarray.char [47].

val int16_unsigned : (int, int16_unsigned_elt) kind

> See Bigarray.char [47].

val int : (int, int_elt) kind

> See Bigarray.char [47].

val int32 : (int32, int32_elt) kind

> See Bigarray.char [47].

val int64 : (int64, int64_elt) kind

> See Bigarray.char [47].

val nativeint : (nativeint, nativeint_elt) kind

> See Bigarray.char [47].

val char : (char, int8_unsigned_elt) kind

> As shown by the types of the values above, big arrays of kind float32_elt and float64_elt are accessed using the Caml type float . Big arrays of complex kinds complex32_elt , complex64_elt are accessed with the Caml type Complex.t [10]. Big arrays of integer kinds are accessed using the smallest Caml integer type large enough to represent the array elements: int for 8- and 16-bit integer bigarrays, as well as Caml-integer bigarrays; int32 for 32-bit integer bigarrays; int64 for 64-bit integer bigarrays; and nativeint for platform-native integer bigarrays. Finally, big arrays of kind int8_unsigned_elt can also be accessed as arrays of characters instead of arrays of small integers, by using the kind value char instead of int8_unsigned .

Array layouts

type c_layout

> See Bigarray.fortran_layout [47].

165

type fortran_layout

To facilitate interoperability with existing C and Fortran code, this library supports two
di erent memory layouts for big arrays, one compatible with the C conventions, the other
compatible with the Fortran conventions.

In the C-style layout, array indices start at 0, and multi-dimensional arrays are laid out in
row-major format. That is, for a two-dimensional array, all elements of row 0 are contiguous
in memory, followed by all elements of row 1, etc. In other terms, the array elements at
(x,y) and (x, y+1) are adjacent in memory.

In the Fortran-style layout, array indices start at 1, and multi-dimensional arrays are laid
out in column-major format. That is, for a two-dimensional array, all elements of column 0
are contiguous in memory, followed by all elements of column 1, etc. In other terms, the
array elements at (x,y) and (x+1, y) are adjacent in memory.

Each layout style is identi ed at the type level by the abstract types Bigarray.c_layout [47]
and fortran_layout respectively.

type 'a layout

The type 'a layout represents one of the two supported memory layouts: C-style i 'a is
Bigarray.c_layout [47], Fortran-style if 'a is Bigarray.fortran_layout [47].

Supported layouts
The abstract values c_layout and fortran_layout represent the two supported layouts at the
level of values.

val c_layout : c_layout layout

val fortran_layout : fortran_layout layout
Generic arrays (of arbitrarily many dimensions)

module Genarray :
  sig

    type ('a, 'b, 'c) t

      The type Genarray.t is the type of big arrays with variable numbers of dimensions.
      Any number of dimensions between 1 and 16 is supported.
      The three type parameters to Genarray.t identify the array element kind and layout,
      as follows:

        • the rst parameter, 'a , is the Caml type for accessing array elements float , int ,
          int32 , int64 , nativeint);
        • the second parameter, 'b , is the actual kind of array elements (float32_elt ,
          float64_elt , int8_signed_elt , int8_unsigned_elt , etc);
        • the third parameter, 'c , identi es the array layout (c_layout or fortran_layout).

      For instance, (float, float32_elt, fortran_layout) Genarray.t is the type of
      generic big arrays containing 32-bit oats in Fortran layout; reads and writes in this
      array use the Caml type float .

val create :
  ('a, 'b) Bigarray.kind ->
  'c Bigarray.layout -> int array -> ('a, 'b, 'c) t

> Genarray.create kind layout dimensions returns a new big array whose element
> kind is determined by the parameter kind (one of float32 , float64 , int8_signed , etc)
> and whose layout is determined by the parameter layout (one of c_layout or
> fortran_layout). The dimensions parameter is an array of integers that indicate the
> size of the big array in each dimension. The length of dimensions determines the
> number of dimensions of the bigarray.
>
> For instance, Genarray.create int32 c_layout [|4;6;8|] returns a fresh big array
> of 32-bit integers, in C layout, having three dimensions, the three dimensions being 4, 6
> and 8 respectively.
>
> Big arrays returned by Genarray.create are not initialized: the initial values of array
> elements is unspeci ed.
>
> Genarray.create raises Invalid_argument if the number of dimensions is not in the
> range 1 to 16 inclusive, or if one of the dimensions is negative.

val num_dims : ('a, 'b, 'c) t -> int

> Return the number of dimensions of the given big array.

val dims : ('a, 'b, 'c) t -> int array

> Genarray.dims a returns all dimensions of the big array a, as an array of integers of
> length Genarray.num_dims a

val nth_dim : ('a, 'b, 'c) t -> int -> int

> Genarray.nth_dim a n returns the n-th dimension of the big array a. The rst
> dimension corresponds to n = 0; the second dimension corresponds to n = 1; the last
> dimension, to n = Genarray.num_dims a - 1. Raise Invalid_argument if n is less
> than 0 or greater or equal than Genarray.num_dims a

val kind : ('a, 'b, 'c) t -> ('a, 'b) Bigarray.kind

> Return the kind of the given big array.

val layout : ('a, 'b, 'c) t -> 'c Bigarray.layout

> Return the layout of the given big array.

val get : ('a, 'b, 'c) t -> int array -> 'a

> Read an element of a generic big array. Genarray.get a [|i1; ...; iN|] returns the
> element of a whose coordinates are i1 in the rst dimension, i2 in the second
> dimension, . . ., iN in the N-th dimension.
>
> If a has C layout, the coordinates must be greater or equal than 0 and strictly less than
> the corresponding dimensions of a. If a has Fortran layout, the coordinates must be

greater or equal than 1 and less or equal than the corresponding dimensions of a. Raise `Invalid_argument` if the array a does not have exactly N dimensions, or if the coordinates are outside the array bounds.

If N > 3, alternate syntax is provided: you can write `a.{i1, i2, ..., iN}` instead of `Genarray.get a [|i1; ...; iN|]`. (The syntax `a.{...}` with one, two or three coordinates is reserved for accessing one-, two- and three-dimensional arrays as described below.)

`val set : ('a, 'b, 'c) t -> int array -> 'a -> unit`

Assign an element of a generic big array. `Genarray.set a [|i1; ...; iN|] v` stores the value v in the element of a whose coordinates are i1 in the first dimension, i2 in the second dimension, ..., iN in the N-th dimension.

The array a must have exactly N dimensions, and all coordinates must lie inside the array bounds, as described for `Genarray.get`; otherwise, `Invalid_argument` is raised.

If N > 3, alternate syntax is provided: you can write `a.{i1, i2, ..., iN} <- v` instead of `Genarray.set a [|i1; ...; iN|] v`. (The syntax `a.{...} <- v` with one, two or three coordinates is reserved for updating one-, two- and three-dimensional arrays as described below.)

`val sub_left :`
`  ('a, 'b, Bigarray.c_layout) t ->`
`  int -> int -> ('a, 'b, Bigarray.c_layout) t`

Extract a sub-array of the given big array by restricting the first (left-most) dimension. `Genarray.sub_left a ofs len` returns a big array with the same number of dimensions as a, and the same dimensions as a, except the first dimension, which corresponds to the interval `[ofs ... ofs + len - 1]` of the first dimension of a. No copying of elements is involved: the sub-array and the original array share the same storage space. In other terms, the element at coordinates `[|i1; ...; iN|]` of the sub-array is identical to the element at coordinates `[|i1+ofs; ...; iN|]` of the original array a.

`Genarray.sub_left` applies only to big arrays in C layout. Raise `Invalid_argument` if ofs and len do not designate a valid sub-array of a, that is, if ofs < 0, or len < 0, or ofs + len > `Genarray.nth_dim a 0`.

`val sub_right :`
`  ('a, 'b, Bigarray.fortran_layout) t ->`
`  int -> int -> ('a, 'b, Bigarray.fortran_layout) t`

Extract a sub-array of the given big array by restricting the last (right-most) dimension. `Genarray.sub_right a ofs len` returns a big array with the same number of dimensions as a, and the same dimensions as a, except the last dimension, which corresponds to the interval `[ofs ... ofs + len - 1]` of the last dimension of a. No copying of elements is involved: the sub-array and the original array share the same storage space. In other terms, the element at coordinates `[|i1; ...; iN|]` of the

sub-array is identical to the element at coordinates $[|i1; ...; iN+ofs|]$ of the original array a.

Genarray.sub_right applies only to big arrays in Fortran layout. Raise Invalid_argument if ofs and len do not designate a valid sub-array of a, that is, if ofs < 1, or len < 0, or ofs + len > Genarray.nth_dim a (Genarray.num_dims a - 1) .

val slice_left :
  ('a, 'b, Bigarray.c_layout) t ->
  int array -> ('a, 'b, Bigarray.c_layout) t

Extract a sub-array of lower dimension from the given big array by fixing one or several of the first (left-most) coordinates. Genarray.slice_left a $[|i1; ... ; iM|]$ returns the slice of a obtained by setting the first M coordinates to $i1$, ..., iM. If a has N dimensions, the slice has dimension $N - M$, and the element at coordinates $[|j1; ...; j(N-M)|]$ in the slice is identical to the element at coordinates $[|i1; ...; iM; j1; ...; j(N-M)|]$ in the original array a. No copying of elements is involved: the slice and the original array share the same storage space.

Genarray.slice_left applies only to big arrays in C layout. Raise Invalid_argument if M >= N, or if $[|i1; ... ; iM|]$ is outside the bounds of a.

val slice_right :
  ('a, 'b, Bigarray.fortran_layout) t ->
  int array -> ('a, 'b, Bigarray.fortran_layout) t

Extract a sub-array of lower dimension from the given big array by fixing one or several of the last (right-most) coordinates. Genarray.slice_right a $[|i1; ... ; iM|]$ returns the slice of a obtained by setting the last M coordinates to $i1$, ..., iM. If a has N dimensions, the slice has dimension $N - M$, and the element at coordinates $[|j1; ...; j(N-M)|]$ in the slice is identical to the element at coordinates $[|j1; ...; j(N-M); i1; ...; iM|]$ in the original array a. No copying of elements is involved: the slice and the original array share the same storage space.

Genarray.slice_right applies only to big arrays in Fortran layout. Raise Invalid_argument if M >= N, or if $[|i1; ... ; iM|]$ is outside the bounds of a.

val blit : ('a, 'b, 'c) t -> ('a, 'b, 'c) t -> unit

Copy all elements of a big array in another big array. Genarray.blit src dst copies all elements of src into dst. Both arrays src and dst must have the same number of dimensions and equal dimensions. Copying a sub-array of src to a sub-array of dst can be achieved by applying Genarray.blit to sub-array or slices of src and dst.

val fill : ('a, 'b, 'c) t -> 'a -> unit

Set all elements of a big array to a given value. Genarray.fill a v stores the value v in all elements of the big array a. Setting only some elements of a to v can be achieved by applying Genarray.fill to a sub-array or a slice of a.

```
val  map_file  :
    Unix.file_descr  ->
    ?pos:int64  ->
    ('a, 'b) Bigarray.kind  ->
    'c Bigarray.layout  ->  bool  ->  int  array  ->  ('a, 'b, 'c) t
```

Memory mapping of a le as a big array. Genarray.map_file fd kind layout shared
dims returns a big array of kind kind , layout layout , and dimensions as speci ed in
dims. The data contained in this big array are the contents of the le referred to by the
 le descriptor fd (as opened previously withUnix.openfile   , for example). The
optional pos parameter is the byte o set in the le of the data being mapped; it
defaults to 0 (map from the beginning of the le).

If shared is true , all modi cations performed on the array are re ected in the le.
This requires that fd be opened with write permissions. Ifshared is false ,
modi cations performed on the array are done in memory only, using copy-on-write of
the modi ed pages; the underlying le is not a ected.

Genarray.map_file   is much more e cient than reading the whole le in a big array,
modifying that big array, and writing it afterwards.

To adjust automatically the dimensions of the big array to the actual size of the le,
the major dimension (that is, the rst dimension for an array with C layout, and the
last dimension for an array with Fortran layout) can be given as-1 .
Genarray.map_file   then determines the major dimension from the size of the le. The
 le must contain an integral number of sub-arrays as determined by the non-major
dimensions, otherwiseFailure   is raised.

If all dimensions of the big array are given, the le size is matched against the size of
the big array. If the le is larger than the big array, only the initial portion of the le is
mapped to the big array. If the le is smaller than the big array, the le is
automatically grown to the size of the big array. This requires write permissions onfd .

end

One-dimensional arrays

module Array1 :
  sig

    type ('a, 'b, 'c) t

        The type of one-dimensional big arrays whose elements have Caml type'a ,
        representation kind 'b , and memory layout 'c .

    val create :
        ('a, 'b) Bigarray.kind ->
        'c Bigarray.layout -> int -> ('a, 'b, 'c) t

        Array1.create kind layout dim   returns a new bigarray of one dimension, whose size
        is dim. kind and layout   determine the array element kind and the array layout as
        described forGenarray.create .

170
```

val dim : ('a, 'b, 'c) t -> int

   Return the size (dimension) of the given one-dimensional big array.

val kind : ('a, 'b, 'c) t -> ('a, 'b) Bigarray.kind

   Return the kind of the given big array.

val layout : ('a, 'b, 'c) t -> 'c Bigarray.layout

   Return the layout of the given big array.

val get : ('a, 'b, 'c) t -> int -> 'a

   Array1.get a x , or alternatively a.{x} , returns the element of a at index x. x must be
   greater or equal than 0 and strictly less than Array1.dim a if a has C layout. If a has
   Fortran layout, x must be greater or equal than 1 and less or equal than Array1.dim a .
   Otherwise, Invalid_argument is raised.

val set : ('a, 'b, 'c) t -> int -> 'a -> unit

   Array1.set a x v , also written a.{x} <- v , stores the value v at index x in a. x must
   be inside the bounds of a as described in Bigarray.Array1.get [47]; otherwise,
   Invalid_argument is raised.

val sub : ('a, 'b, 'c) t ->
  int -> int -> ('a, 'b, 'c) t

   Extract a sub-array of the given one-dimensional big array. See Genarray.sub_left for
   more details.

val blit : ('a, 'b, 'c) t -> ('a, 'b, 'c) t -> unit

   Copy the rst big array to the second big array. See Genarray.blit for more details.

val fill : ('a, 'b, 'c) t -> 'a -> unit

   Fill the given big array with the given value. See Genarray.fill for more details.

val of_array :
  ('a, 'b) Bigarray.kind ->
  'c Bigarray.layout -> 'a array -> ('a, 'b, 'c) t

   Build a one-dimensional big array initialized from the given array.

val map_file :
  Unix.file_descr ->
  ?pos:int64 ->
  ('a, 'b) Bigarray.kind ->
  'c Bigarray.layout -> bool -> int -> ('a, 'b, 'c) t

171

Memory mapping of a le as a one-dimensional big array. See
Bigarray.Genarray.map_file    [47] for more details.

val unsafe_get : ('a, 'b, 'c) t -> int -> 'a

Like Bigarray.Array1.get    [47], but bounds checking is not always performed. Use with
caution and only when the program logic guarantees that the access is within bounds.

val unsafe_set : ('a, 'b, 'c) t -> int -> 'a -> unit

Like Bigarray.Array1.set    [47], but bounds checking is not always performed. Use with
caution and only when the program logic guarantees that the access is within bounds.

end

One-dimensional arrays. The Array1 structure provides operations similar to those of
Bigarray.Genarray [47], but specialized to the case of one-dimensional arrays. (The Array2
and Array3 structures below provide operations specialized for two- and three-dimensional
arrays.) Statically knowing the number of dimensions of the array allows faster operations,
and more precise static type-checking.

Two-dimensional arrays

module Array2 :
  sig

type ('a, 'b, 'c) t

The type of two-dimensional big arrays whose elements have Caml type 'a ,
representation kind 'b , and memory layout 'c .

val create :
  ('a, 'b) Bigarray.kind ->
  'c Bigarray.layout -> int -> int -> ('a, 'b, 'c) t

Array2.create kind layout dim1 dim2    returns a new bigarray of two dimension,
whose size is dim1 in the rst dimension and dim2 in the second dimension. kind and
layout determine the array element kind and the array layout as described for
Bigarray.Genarray.create    [47].

val dim1 : ('a, 'b, 'c) t -> int

Return the rst dimension of the given two-dimensional big array.

val dim2 : ('a, 'b, 'c) t -> int

Return the second dimension of the given two-dimensional big array.

val kind : ('a, 'b, 'c) t -> ('a, 'b) Bigarray.kind

Return the kind of the given big array.

172

val layout : ('a, 'b, 'c) t -> 'c Bigarray.layout

> Return the layout of the given big array.

val get : ('a, 'b, 'c) t -> int -> int -> 'a

> Array2.get a x y , also written a.{x,y} , returns the element of a at coordinates (x, y). x and y must be within the bounds of a, as described for Bigarray.Genarray.get [47]; otherwise, Invalid_argument is raised.

val set : ('a, 'b, 'c) t -> int -> int -> 'a -> unit

> Array2.set a x y v , or alternatively a.{x,y} <- v , stores the value v at coordinates (x, y) in a. x and y must be within the bounds of a, as described for Bigarray.Genarray.set [47]; otherwise, Invalid_argument is raised.

val sub_left :
  ('a, 'b, Bigarray.c_layout) t ->
  int -> int -> ('a, 'b, Bigarray.c_layout) t

> Extract a two-dimensional sub-array of the given two-dimensional big array by restricting the  rst dimension. See Bigarray.Genarray.sub_left [47] for more details. Array2.sub_left applies only to arrays with C layout.

val sub_right :
  ('a, 'b, Bigarray.fortran_layout) t ->
  int -> int -> ('a, 'b, Bigarray.fortran_layout) t

> Extract a two-dimensional sub-array of the given two-dimensional big array by restricting the second dimension. See Bigarray.Genarray.sub_right [47] for more details. Array2.sub_right applies only to arrays with Fortran layout.

val slice_left :
  ('a, 'b, Bigarray.c_layout) t ->
  int -> ('a, 'b, Bigarray.c_layout) Bigarray.Array1.t

> Extract a row (one-dimensional slice) of the given two-dimensional big array. The integer parameter is the index of the row to extract. See Bigarray.Genarray.slice_left [47] for more details. Array2.slice_left applies only to arrays with C layout.

val slice_right :
  ('a, 'b, Bigarray.fortran_layout) t ->
  int -> ('a, 'b, Bigarray.fortran_layout) Bigarray.Array1.t

> Extract a column (one-dimensional slice) of the given two-dimensional big array. The integer parameter is the index of the column to extract. See Bigarray.Genarray.slice_right [47] for more details. Array2.slice_right applies only to arrays with Fortran layout.

val blit : ('a, 'b, 'c) t -> ('a, 'b, 'c) t -> unit

Copy the  rst big array to the second big array. SeeBigarray.Genarray.blit    [47] for
more details.

val fill : ('a, 'b, 'c) t -> 'a -> unit

Fill the given big array with the given value. SeeBigarray.Genarray.fill    [47] for
more details.

val of_array :
  ('a, 'b) Bigarray.kind ->
  'c Bigarray.layout -> 'a array array -> ('a, 'b, 'c) t

Build a two-dimensional big array initialized from the given array of arrays.

val map_file :
  Unix.file_descr ->
  ?pos:int64 ->
  ('a, 'b) Bigarray.kind ->
  'c Bigarray.layout -> bool -> int -> int -> ('a, 'b, 'c) t

Memory mapping of a  le as a two-dimensional big array. See
Bigarray.Genarray.map_file    [47] for more details.

val unsafe_get : ('a, 'b, 'c) t -> int -> int -> 'a

Like Bigarray.Array2.get    [47], but bounds checking is not always performed.

val unsafe_set : ('a, 'b, 'c) t -> int -> int -> 'a -> unit

Like Bigarray.Array2.set    [47], but bounds checking is not always performed.

end

Two-dimensional arrays. TheArray2 structure provides operations similar to those of
Bigarray.Genarray  [47], but specialized to the case of two-dimensional arrays.

Three-dimensional arrays
module Array3 :
  sig

type ('a, 'b, 'c) t

The type of three-dimensional big arrays whose elements have Caml type'a ,
representation kind 'b , and memory layout 'c .

val create :
  ('a, 'b) Bigarray.kind ->
  'c Bigarray.layout -> int -> int -> int -> ('a, 'b, 'c) t

Array3.create kind layout dim1 dim2 dim3 returns a new bigarray of three dimension, whose size is dim1 in the first dimension, dim2 in the second dimension, and dim3 in the third. kind and layout determine the array element kind and the array layout as described for Bigarray.Genarray.create [47].

val dim1 : ('a, 'b, 'c) t -> int

Return the first dimension of the given three-dimensional big array.

val dim2 : ('a, 'b, 'c) t -> int

Return the second dimension of the given three-dimensional big array.

val dim3 : ('a, 'b, 'c) t -> int

Return the third dimension of the given three-dimensional big array.

val kind : ('a, 'b, 'c) t -> ('a, 'b) Bigarray.kind

Return the kind of the given big array.

val layout : ('a, 'b, 'c) t -> 'c Bigarray.layout

Return the layout of the given big array.

val get : ('a, 'b, 'c) t -> int -> int -> int -> 'a

Array3.get a x y z, also written a.{x,y,z}, returns the element of a at coordinates (x, y, z). x, y and z must be within the bounds of a, as described for Bigarray.Genarray.get [47]; otherwise, Invalid_argument is raised.

val set : ('a, 'b, 'c) t -> int -> int -> int -> 'a -> unit

Array3.set a x y v, or alternatively a.{x,y,z} <- v, stores the value v at coordinates (x, y, z) in a. x, y and z must be within the bounds of a, as described for Bigarray.Genarray.set [47]; otherwise, Invalid_argument is raised.

val sub_left :
  ('a, 'b, Bigarray.c_layout) t ->
  int -> int -> ('a, 'b, Bigarray.c_layout) t

Extract a three-dimensional sub-array of the given three-dimensional big array by restricting the first dimension. See Bigarray.Genarray.sub_left [47] for more details. Array3.sub_left applies only to arrays with C layout.

val sub_right :
  ('a, 'b, Bigarray.fortran_layout) t ->
  int -> int -> ('a, 'b, Bigarray.fortran_layout) t

Extract a three-dimensional sub-array of the given three-dimensional big array by restricting the second dimension. See Bigarray.Genarray.sub_right [47] for more details. Array3.sub_right applies only to arrays with Fortran layout.

val slice_left_1 :
  ('a, 'b, Bigarray.c_layout) t ->
  int -> int -> ('a, 'b, Bigarray.c_layout) Bigarray.Array1.t

Extract a one-dimensional slice of the given three-dimensional big array by  xing the
 rst two coordinates. The integer parameters are the coordinates of the slice to extract.
SeeBigarray.Genarray.slice_left      [47] for more details. Array3.slice_left_1
applies only to arrays with C layout.

val slice_right_1 :
  ('a, 'b, Bigarray.fortran_layout) t ->
  int -> int -> ('a, 'b, Bigarray.fortran_layout) Bigarray.Array1.t

Extract a one-dimensional slice of the given three-dimensional big array by  xing the
last two coordinates. The integer parameters are the coordinates of the slice to extract.
SeeBigarray.Genarray.slice_right      [47] for more details. Array3.slice_right_1
applies only to arrays with Fortran layout.

val slice_left_2 :
  ('a, 'b, Bigarray.c_layout) t ->
  int -> ('a, 'b, Bigarray.c_layout) Bigarray.Array2.t

Extract a two-dimensional slice of the given three-dimensional big array by  xing the
 rst coordinate. The integer parameter is the  rst coordinate of the slice to extract.
SeeBigarray.Genarray.slice_left      [47] for more details. Array3.slice_left_2
applies only to arrays with C layout.

val slice_right_2 :
  ('a, 'b, Bigarray.fortran_layout) t ->
  int -> ('a, 'b, Bigarray.fortran_layout) Bigarray.Array2.t

Extract a two-dimensional slice of the given three-dimensional big array by  xing the
last coordinate. The integer parameter is the coordinate of the slice to extract. See
Bigarray.Genarray.slice_right      [47] for more details. Array3.slice_right_2      applies
only to arrays with Fortran layout.

val blit : ('a, 'b, 'c) t -> ('a, 'b, 'c) t -> unit

Copy the  rst big array to the second big array. SeeBigarray.Genarray.blit      [47] for
more details.

val fill : ('a, 'b, 'c) t -> 'a -> unit

Fill the given big array with the given value. SeeBigarray.Genarray.fill      [47] for
more details.

val of_array :
  ('a, 'b) Bigarray.kind ->
  'c Bigarray.layout -> 'a array array array -> ('a, 'b, 'c) t

Build a three-dimensional big array initialized from the given array of arrays of arrays.

```
val map_file :
  Unix.file_descr ->
  ?pos:int64 ->
  ('a, 'b) Bigarray.kind ->
  'c Bigarray.layout ->
  bool -> int -> int -> int -> ('a, 'b, 'c) t
```

Memory mapping of a le as a three-dimensional big array. See Bigarray.Genarray.map_file [47] for more details.

```
val unsafe_get : ('a, 'b, 'c) t -> int -> int -> int -> 'a
```

Like Bigarray.Array3.get [47], but bounds checking is not always performed.

```
val unsafe_set : ('a, 'b, 'c) t -> int -> int -> int -> 'a -> unit
```

Like Bigarray.Array3.set [47], but bounds checking is not always performed.

end

Three-dimensional arrays. TheArray3 structure provides operations similar to those of Bigarray.Genarray [47], but specialized to the case of three-dimensional arrays.

Coercions between generic big arrays and xed-dimension big arrays

```
val genarray_of_array1 : ('a, 'b, 'c) Array1.t -> ('a, 'b, 'c) Genarray.t
```

Return the generic big array corresponding to the given one-dimensional big array.

```
val genarray_of_array2 : ('a, 'b, 'c) Array2.t -> ('a, 'b, 'c) Genarray.t
```

Return the generic big array corresponding to the given two-dimensional big array.

```
val genarray_of_array3 : ('a, 'b, 'c) Array3.t -> ('a, 'b, 'c) Genarray.t
```

Return the generic big array corresponding to the given three-dimensional big array.

```
val array1_of_genarray : ('a, 'b, 'c) Genarray.t -> ('a, 'b, 'c) Array1.t
```

Return the one-dimensional big array corresponding to the given generic big array. Raise Invalid_argument if the generic big array does not have exactly one dimension.

```
val array2_of_genarray : ('a, 'b, 'c) Genarray.t -> ('a, 'b, 'c) Array2.t
```

Return the two-dimensional big array corresponding to the given generic big array. Raise Invalid_argument if the generic big array does not have exactly two dimensions.

```
val array3_of_genarray : ('a, 'b, 'c) Genarray.t -> ('a, 'b, 'c) Array3.t
```

Return the three-dimensional big array corresponding to the given generic big array. Raise Invalid_argument if the generic big array does not have exactly three dimensions.

Re-shaping big arrays

val reshape :
  ('a, 'b, 'c) Genarray.t ->
  int array -> ('a, 'b, 'c) Genarray.t

> reshape b [|d1;...;dN|]   converts the big array b to a N-dimensional array of dimensions
> d1. . .dN The returned array and the original array b share their data and have the same
> layout. For instance, assuming that b is a one-dimensional array of dimension 12, reshape b
> [|3;4|]   returns a two-dimensional array b' of dimensions 3 and 4. If b has C layout, the
> element (x,y)   of b' corresponds to the element x * 3 + y of b. If b has Fortran layout, the
> element (x,y)   of b' corresponds to the element x + (y - 1) * 4   of b. The returned big
> array must have exactly the same number of elements as the original big array b. That is,
> the product of the dimensions of b must be equal to i1 * ...   * iN   . Otherwise,
> Invalid_argument   is raised.

val reshape_1 : ('a, 'b, 'c) Genarray.t -> int -> ('a, 'b, 'c) Array1.t

> Specialized version of Bigarray.reshape [47] for reshaping to one-dimensional arrays.

val reshape_2 :
  ('a, 'b, 'c) Genarray.t ->
  int -> int -> ('a, 'b, 'c) Array2.t

> Specialized version of Bigarray.reshape [47] for reshaping to two-dimensional arrays.

val reshape_3 :
  ('a, 'b, 'c) Genarray.t ->
  int -> int -> int -> ('a, 'b, 'c) Array3.t

> Specialized version of Bigarray.reshape [47] for reshaping to three-dimensional arrays.

48   Module Num: Operation on arbitrary-precision numbers.

Numbers (type num) are arbitrary-precision rational numbers, plus the special elements 1/0 (infinity)
and 0/0 (undefined).

type num =
  | Int of int
  | Big_int of Big_int.big_int
  | Ratio of Ratio.ratio

> The type of numbers.

Arithmetic operations

val (+/) : num -> num -> num

> Same as Num.add_num [48].

val add_num : num -> num -> num

Addition

val minus_num : num -> num
        Unary negation.

val (-/) : num -> num -> num
        Same as Num.sub_num [48].

val sub_num : num -> num -> num
        Subtraction

val (*/) : num -> num -> num
        Same as Num.mult_num [48].

val mult_num : num -> num -> num
        Multiplication

val square_num : num -> num
        Squaring

val (//) : num -> num -> num
        Same as Num.div_num [48].

val div_num : num -> num -> num
        Division

val quo_num : num -> num -> num
        Euclidean division: quotient.

val mod_num : num -> num -> num
        Euclidean division: remainder.

val (**/) : num -> num -> num
        Same as Num.power_num [48].

val power_num : num -> num -> num
        Exponentiation

val abs_num : num -> num
        Absolute value.

val succ_num : num -> num
        succ n is n+1

val pred_num : num -> num

pred n is n-1

val incr_num : num Pervasives.ref -> unit
        incr r   is r:=!r+1   , where r is a reference to a number.

val decr_num : num Pervasives.ref -> unit
        decr r is r:=!r-1   , where r is a reference to a number.

val is_integer_num : num -> bool
        Test if a number is an integer

    The four following functions approximate a number by an integer :
val integer_num : num -> num
        integer_num n returns the integer closest to n. In case of ties, rounds towards zero.

val floor_num : num -> num
        floor_num n returns the largest integer smaller or equal to n.

val round_num : num -> num
        round_num n returns the integer closest to n. In case of ties, rounds o zero.

val ceiling_num : num -> num
        ceiling_num n returns the smallest integer bigger or equal to n.

val sign_num : num -> int
        Return -1 , 0 or 1 according to the sign of the argument.

    Comparisons between numbers
val (=/) : num -> num -> bool
val (</) : num -> num -> bool
val (>/) : num -> num -> bool
val (<=/) : num -> num -> bool
val (>=/) : num -> num -> bool
val (<>/) : num -> num -> bool
val eq_num : num -> num -> bool
val lt_num : num -> num -> bool
val le_num : num -> num -> bool
val gt_num : num -> num -> bool
val ge_num : num -> num -> bool
val compare_num : num -> num -> int
        Return -1 , 0 or 1 if the rst argument is less than, equal to, or greater than the second
        argument.

val max_num : num -> num -> num

    Return the greater of the two arguments.

val min_num : num -> num -> num

    Return the smaller of the two arguments.

  Coercions with strings

val string_of_num : num -> string

    Convert a number to a string, using fractional notation.

val approx_num_fix : int -> num -> string

    SeeNum.approx_num_exp[48].

val approx_num_exp : int -> num -> string

    Approximate a number by a decimal. The rst argument is the required precision. The second argument is the number to approximate.Num.approx_num_fix[48] uses decimal notation; the rst argument is the number of digits after the decimal point. approx_num_exp uses scienti c (exponential) notation; the rst argument is the number of digits in the mantissa.

val num_of_string : string -> num

    Convert a string to a number.

  Coercions between numerical types

val int_of_num : num -> int

val num_of_int : int -> num

val nat_of_num : num -> Nat.nat

val num_of_nat : Nat.nat -> num

val num_of_big_int : Big_int.big_int -> num

val big_int_of_num : num -> Big_int.big_int

val ratio_of_num : num -> Ratio.ratio

val num_of_ratio : Ratio.ratio -> num

val float_of_num : num -> float
